UNITED STATES DEPARTMENT OF THE INTERIOR • Stewart L. Udall, Secretary

BUREAU OF MINES • Marling J. Ankeny, Director

Created in 1849, the Department of the Interior—a Department of Conservation—is concerned with the management, conservation, and development of the Nation's water, fish, wildlife, mineral, forest, and park and recreational resources. It also has major responsibilities for Indian and Territorial affairs.

As the Nation's principal conservation agency, the Department works to assure that nonrenewable resources are developed and used wisely, that park and recreational resources are conserved for the future, and that renewable resources make their full contribution to the progress, prosperity, and security of the United States—now and in the future.

FOREWORD

The 1963 MINERALS YEARBOOK marks the 82d year in which this publication or its predecessors have been issued by the Federal Government. It also marks the first issue of a fourth volume reviewing world mineral production, consumption, and trade on a country-by-country basis. This new international review volume represents the Bureau's continuing effort to make the Yearbook as useful as possible to industry, Government and the general public.

Many difficulties had to be surmounted in preparing this new volume. Although it has not been possible in several instances to present international data comparable to those available for the United States, the international review should nevertheless prove a valuable reference.

The general content of this four-volume edition is as follows:

Volume I contains chapters on metal and on nonmetal mineral commodities except mineral fuels. In addition, it includes a chapter reviewing these mineral industries, a statistical summary, and chapters on mining and metallurgical technology, employment and injuries, and technologic trends.

Volume II contains a chapter on each mineral fuel and on such related products as helium, carbon black, peat, coke and coal chemicals, and natural gas liquids. Also included are data on employment and injuries in the fuel industries, and a mineral-fuels review summarizing recent economic and technological developments.

Volume III contains chapters covering each of the 50 States, United States island possessions in the Pacific Ocean, the Commonwealth of Puerto Rico, and island possessions in the Caribbean Sea, including the Canal Zone. Volume III also has a statistical summary chapter, identical with that in Volume I, and a chapter on employment and injuries.

Volume IV contains 124 chapters presenting the latest available mineral statistics for more than 130 foreign countries and areas, and 1 chapter reviewing minerals in the world economy.

To my knowledge, the Minerals Yearbook is the most comprehensive publication of its kind available. The Bureau will continue its efforts in the years to come to increase the Yearbook's value to its many users. Toward that end, the constructive comments and suggestions of readers will be helpful.

MARLING J. ANKENY, *Director.*

ACKNOWLEDGMENTS

The Bureau of Mines acknowledges the assistance in the preparation of this volume of many mineral agencies abroad and the official publications on statistical data and other subjects issued in these countries. Many useful data were obtained from publications of the United Nations and the technical publications originating in the United States and many other countries. Information obtained from dispatches from the Embassies of the Department of State the world over is acknowledged. Particularly useful are routine and special reports received from technical, mineral, and petroleum attaches who usually report on several countries in their respective areas. The attache services comprise:

Burton E. Ashley, Attache, Minerals Reporting Officer, Canberra, Australia.
W. Charles Bridgett, Attache, Petroleum Officer, Caracas, Venezuela.
John Burgess, Jr., Attache, Technical Minerals Specialist, Lima, Peru.
Donald F. Campbell, Attache, Minerals Reporting Officer, La Paz, Bolivia.
Bryan R. Frisbie, Attache, Technical Minerals Specialist, New Delhi, India.
William F. Keyes, Consul, Technical Minerals Specialist, Johannesburg, Republic of South Africa.
Edgar L. McGinnis, First Secretary, Petroleum Officer, London, England.
Charles D. Mueller, Second Secretary, Consul, Minerals Reporting Officer, Mexico D. F., Mexico.
Roderick G. Murchison, Jr., Minerals Attache, Technical Minerals Specialist, Accra, Ghana.
Martin Prochnik, Second Secretary, Minerals Reporting Officer, Santiago, Chile.
Alfred L. Ransome, Minerals Attache, Technical Minerals Specialist, Rio de Janeiro, Brazil.
Clarence A. Wendel, Attache, Technical Minerals Specialist, Ankara, Turkey.
Dawson S. Wilson, Second Secretary, Minerals Reporting Officer, Manila, Philippines.

Basic data on production and trade of minerals (metals, nonmetals, and fuels) in foreign countries were in many cases supplied by the International Statistics Staff, supervised by Berenice B. Mitchell, and including Helen L. Hunt, Pearl J. Thompson, Liela S. Price, and Virginia G. Huguley on foreign production; and Corra A. Barry, Bertha M. Duggan, Agnes M. Chaney, and Victoria R. Schreck on foreign trade. Also data on trade in many areas were obtained, correlated and compiled by Agnes J. Doughman, Gertrude N. Greenspoon, and Mary E. Trought.

The individual chapters for this volume were prepared by the staff of the Division of International Activities and were coordinated and reviewed by Louis A. Turnbull, Charles L. Kimbell, and Edgar J. Gealy. The correlation and final checking of material for Volume IV to meet Minerals Yearbook standards were made in the Division of

Minerals in the World Economy

By Stephen C. Brown[1]

THE expansion of the world economy which has been in progress since 1958 continued in 1963 and both production and consumption of minerals rose. Gross national product (GNP) rose sharply in the United Kingdom and Japan, continued to expand in the United States and Canada, and maintained a high though slightly declining rate of growth in the European Economic Community (EEC) despite the appearance of excess capacity in certain lines and inflationary pressures in Italy and France. The steel and motor vehicle industries both increased output in North America, Western Europe, and Japan. The less developed areas benefited substantially from an improvement in their terms of trade, and their export earnings increased some 8 percent in 1963; although estimates of GNP for the majority of them are not yet available, it is probable that this increase was partly reflected in a substantial rise of GNP.[2]

In the United States the expansion was steady and extended through all sectors of the economy producing no distortions likely to disturb its continuing growth; at yearend with unemployment still at about 5.5 percent of the labor force and operating rates of industry estimated at about 87 percent of capacity, there was a substantial margin for further expansion. Though the balance of payments was still in heavy deficit for the year, in the last half it was moving rapidly toward equalibrium as net exports rose and capital outflows declined; prices were relatively stable, inventories increased only slightly and the activity of mineral-consuming industries remained high, steel output rising by 11 percent to highest level since 1957 and the auto industry output equalling the 1955 record.[3]

The economic expansion outside the United States contained some elements of greater uncertainty. The rapid rise of the United King-

dom's output was accompanied by growing pressure on labor supplies, rising wage rates, and a widening trade gap as producers began to restock their inventories of raw materials toward the end of the year. The prospects of a further expansion of demand that might put excessive strain on resources and the balance of payments caused authorities to consider a slight cutback in the growth rate in 1964. In the EEC the overall expansion of the economy by 4 percent in 1963 concealed mounting inflationary pressures, continuing wage rises, and accelerating consumer price increases which led authorities, particularly in Italy and France, to take action to restrict the pressures of demand; the trade deficit with non-EEC countries doubled from US$1,500 million in 1962 to US$3,000 million in 1963 and the balance of payments surplus on trade and factor income was reduced to about US$500 million. A 19 percent increase in fuel imports from non-EEC sources was a major factor in the deterioration of the balance of payments. In Japan, too, the high rate of growth in 1963 had led to a large increase in imports, a widening of the adverse trade balance, and rising inflationary pressures; Japanese authorities (like the British authorities) decided that the rate of growth must be cut back slightly.[4]

The primary producing and less industrialized countries had a better year than in 1962 or for some years past, and benefited from a general rise in the prices of their export products. The volume of their exports continued to increase and import prices changed little. Their terms of trade improved by practically the full amount of the commodity price increases, bringing them back to the level of 1961, and about 10 percent below the high levels of 1950. Export earnings increased and the balances of payments generally improved; although the bulk of the increases in monetary reserves was concentrated in a few countries, the majority of the primary producers recorded somewhat higher reserves. Benefiting from a rise in the volume of petroleum exports, though not from price increases, the oil producers fared somewhat better than most other primary producers.[5]

Much of the improvement in commodity prices and the terms of trade of the less developed countries apparently can be traced to the effects of weather, and caution should therefore be exercised in interpreting it as a continuing trend. The abnormally cold Northern Hemisphere winter of 1962–63 had an adverse effect on crops there, as did the prevalence of drought in some regions; while the cold winter (coupled with a French coal strike early in the year) sharply increased European requirements for fuel imports. Only the improvement in nonferrous metal prices appeared to reflect a changing basic supply

and demand position, as the continuing high level of world industrial output began to catch up with the excess production capacity created during the 1950's.

The developing pattern of the free world economy in 1963 thus showed a continuing strong expansion in the United States and in Canada, a strong rise in the United Kingdom and Japan which the authorities of both countries believed must be restrained primarily for balance of payments reasons, and a slightly smaller rate of expansion in the EEC than during 1962, a rate whose maintenance may be affected by efforts to restrain internal inflationary pressures. All three of the areas outside North America, more dependent than the United States and Canada on imported raw materials, and all subject in some degree to inflationary pressures in 1963, appeared to be moving towards balance of payments deficits. The U.S. balance appeared finally to be moving towards equilibrium though still in heavy deficit. The convergence of growth rates in the neighborhood of 4 to 5 percent thus appeared to represent different cyclical phases in the growth trend of the free world economy.

Despite the rise of smaller industrial centers in Australia, India, South Africa, Brazil, Mexico, and a few other countries, the United States, Western Europe, and Japan remain the chief motive forces in the free world economy and their requirements are the principal determinants of demand for minerals. Together they account for about two-thirds of the free world's imports of ores, metals, and fuels. The developments of the past 5 years have brought them into a more balanced relationship, and the U.S. economy is no longer the completely decisive factor that it was for a decade after World War II. In the case of minerals, for example, a continuation of the rising trend in the prices and volume of primary producers' exports depends on continuing high demands from all three areas; of these, the EEC is the largest importer and both the United Kingdom and Japan are important markets.

The economies of the Communist countries in Europe and Asia have also expanded at a high rate during the past 5 years but the nature and structure of their economies, as well as their commercial policies, cause them to participate in the world economy on what is essentially a marginal basis. Their domestic economies are completely and centrally planned, the bulk of production is destined for domestic consumption and use, and surpluses have normally been exported primarily to obtain needed supplies of raw materials, equipment or other goods. Even in such cases surpluses are exchanged chiefly among themselves and are exported outside the group usually in exchange for goods not available within it. For this reason their rates of growth do not normally have the same impact on or importance for the world economy as do those of other regions. More recently, however, Communist external transactions have assumed greater importance as these countries have embarked on programs of economic aid to the less developed countries and have begun to export goods to the free world in order to obtain capital equipment. On the supply side of the mineral industries they have played a significant role in a number of commodities such as petroleum, apatite and potash, manganese, chromite, tungsten, antimony, mercury, and the platinum metals; on the demand

Digitized by Google

side they have been significant importers of copper. Their role may expand if the economic solidarity of the group should dissolve.

The 1963 changes represent for the most part a continuation of trends of previous years. In essence, the trends reflect a period of very rapid growth of the West European and Japanese economies, increasing their overall size and absorbing their domestic resources of raw materials until further growth became dependent on major increases in imports from outside.

The differential growth rates of the three major free world areas have given a new shape and structure to the free world economy. In both Western Europe and Japan powerful investment booms involved a sizable expansion of capacity in major industries, an increasing shift to heavy industry and consumer durables, and a sharply increased consumption of all primary products, especially ores, metals, and fuels. A major development in both areas has been a massive shift from coal to petroleum as a source of energy. The more rapid growth of Western Europe and Japan not only restored them to their prewar positions of eminence in the world economy, but also brought about a redistribution of the world's currency reserves in their favor.[6]

The steady expansion of the world economy since 1958 has also been assisted by the relative stability of commodity prices since the recession of 1957–58, and by the restoration of currency convertibility by the major European countries with the consequent elimination of their exchange controls and quota restrictions. Ample capacity in practically all lines contributed to the stability of prices. This was especially true in minerals, for which investments stimulated by the Korean War actually created surplus capacity. The increasing ease of capital transfers and goods movements stimulated both trade and investment throughout the free world. The net effect was to reintegrate the free world's economies on a scale not seen since 1939.

A rather general measure of the industrial expansion in the past 5 years is given by the United Nations indexes of industrial production.

TABLE 1.—Indexes of world industrial production, by region

(1958=100)

Region	1959	1960	1961	1962	1963 [1]

PRODUCTION

The United Nations index of free world mining production in 1963 rose about 3 percent over 1962 output levels, with the chief increases occurring in iron and steel, aluminum, lead, and the two major fuels. Bureau of Mines data indicate that total world output of steel ingots and castings rose about 7 percent, although iron ore production increased only about 2 percent. Of the minerals associated with the steel industry, output of manganese ore, magnesite, and molybdenite rose, while production of fluorspar, chromite, and ores of vanadium, tungsten, and nickel declined. Among the nonferrous metals, aluminum production continued its growth trend and increased 9 percent though bauxite output declined 2 percent. Total world mine copper output, still under voluntary restrictions and affected by strikes and by political instability in the Republic of the Congo (Leopoldville), rose only about 2 percent. Mine output of lead increased about 1.5 percent and of zinc 2 percent. Mine production of tin increased marginally with small increases in the U.S.S.R., Malaysia, Thailand, Bolivia, and Nigeria offsetting a sharp reduction in Indonesia; the gap between new supply and demand remained, being filled by U.S. stockpile releases and the drawing down of other stocks. Industrial demand pressures also continued on silver, with new production inadequate for requirements and the shortfall being met by U.S. Treasury stocks and other supplies. Gold output rose by 4 percent and silver by 3 percent. Among the nonmetals, total output of sulfur rose by about 2 percent, with a 4 percent increase in output of elemental sulfur more than offsetting a decline in production from pyrites; potash production rose about 11 percent, the main factors being sharp increases in the United States and Canada; while phosphate output rose by about 6 percent, the chief increases occurring in the United States, the U.S.S.R. and Communist Asia, Morocco, and Tunisia. World cement output rose by about 5 percent. Production of coal rose about 4 percent and crude petroleum about 7 percent.[7]

Among free world countries mine output, including petroleum, rose more rapidly during 1963 in the less industrialized countries than in the major industrial areas, reflecting the growing dependence of the latter on ores and minerals from outside their territories; the United Nations index of the volume of mining production for the industrialized countries rose over 1962 levels by 2 percent as compared with a 7 percent rise in the index for less industrialized countries.

In 1963 the output of crude petroleum and natural gas continued to maintain a more rapid rate of growth than coal and metals.

The rates of increase since 1958 in output of the more important minerals, according to United Nations indexes varied substantially.

The United Nations indexes exclude the output of the European and Asian Communist countries and, to that extent, do not reflect accurately the trends of total world production. Data prepared by the Bureau of Mines summarize total world production of 65 major minerals for the years 1959–63, with the averages for the preceding 5 years given for purposes of comparison. The Bureau data include

estimates for European and Asian Communist countries and the coverage is therefore more complete.

In table 6 the percentage distribution of 1963 world production of these minerals among the eight major geographical regions is shown, as well as a breakdown between Western Hemisphere and Eastern Hemisphere production.

TABLE 2.—Indexes of free world mining production, by regions

(1958=100)

Region	1959	1960	1961	1962	1963 [1]
Free World [2]	104	111	117	123	127
Northern North America [3]	104	107	108	112	114
Europe [2]	98	100	102	103	104
EEC	98	101	103	103	102
EFTA	98	96	95	97	97
Japan	99	108	116	118	116
Asia, East and Southeast [4]	110	124	132	144	151
Latin America [5]	106	112	114	122	125
Industrialized countries	103	105	107	110	112
Less industrialized countries	108	130	145	161	172

[1] Preliminary figures.
[2] Excludes European and Asian Communist countries except Yugoslavia.
[3] United States and Canada.
[4] Excludes Japan, Cambodia, Laos, and Asian Communist Bloc; includes Iran, Afghanistan, Pakistan, India, Ceylon, Burma, Thailand, Malaysia (except Sabah), South Viet-Nam, Brunei, Indonesia, Philippines, Hong Kong, Taiwan and Republic of Korea.
[5] Central America, South America, and Caribbean Islands.

TABLE 4.—Indexes of world production of major mineral commodities[1 2]

(1958=100)

Commodity	1959	1960	1961	1962	1963
Aluminum [3]	115	129	126	138	152
Copper (smelter) [4]	106	127	128	132	136
Pig iron	109	124	129	133	141
Steel, crude	111	125	130	133	143
Lead [3]	94	100	104	103	108
Tin [5]	94	119	113	119	119
Zinc [3]	103	107	114	119	121
Coal [6]	100	101	102	105	108
Petroleum (crude)	108	116	123	134	143

[1] United Nations. Monthly Bulletin of Statistics. May 1964, Special Table B.
[2] Excludes mainland China.
[3] Excludes U.S.S.R., Eastern Germany, Czechoslovakia, Rumania, and North Korea.
[4] Excludes U.S.S.R., East Germany, Albania, and North Korea.
[5] Excludes U.S.S.R. and Eastern Europe.
[6] Includes coal equivalent of brown coal and lignite.

TABLE 5.—World production of major minerals

Commodity	1954–58 (average)	1959	1960	1961	1962	1963
Metals:						
Aluminum—thousand metric tons	3,250	4,060	4,530	4,725	5,080	5,530

TABLE 5.—World production of major minerals—Continued

Commodity	1954–58 (average)	1959	1960	1961	1962	1963
Nonmetals						
Asbestos [12]—thousand metric tons	1,765	2,060	2,210	2,510	2,770	2,900
Barite [3]—do	2,655	2,790	2,850	2,860	3,115	2,905
Cement, hydraulic—do	231,277	294,412	316,537	333,428	357,841	375,412
Corundum—do	9	7	8	7	8	10
Diamond, gem—thousand carats	4,742	5,900	6,700	7,000	6,347	6,572
Diamond, industrial—do	19,160	20,900	21,000	27,250	27,659	30,089
Diatomite [13]—thousand metric tons	1,113	1,345	1,410	1,485	1,480	1,465
Feldspar [14]—do	1,230	1,370	1,520	1,550	1,570	1,620
Fluorspar—do	1,620	1,720	2,020	2,070	2,190	2,120
Graphite—do	280	370	430	410	530	660
Gypsum [15]—do	33,260	43,100	42,370	43,300	46,910	48,960
Magnesite—do	4,700	5,500	6,250	7,550	7,800	8,200
Mica—do	140	160	165	165	180	180
Phosphate rock [16]—do	32,700	38,375	41,900	45,475	48,200	51,200
Potash (marketable), K_2O equiv.—do	7,500	8,500	9,100	9,700	9,800	10,900
Pumice [17]—do	7,680	9,700	10,320	11,840	12,250	13,340
Pyrites (incl. cupreous) [18]—do	17,400	18,900	20,100	19,600	20,100	20,000
Salt—do	68,000	79,700	84,900	84,700	91,400	95,100
Strontium minerals (free world) [19] metric tons	10,892	9,700	11,800	12,900	7,800	15,200
Sulfur, native—thousand metric tons	6,459	7,180	7,810	8,440	8,330	8,250
Sulfur, byproduct elemental—do	([10])	2,090	2,710	3,300	3,930	4,475
Talc, soapstone, and pyrophyllite—do	1,835	2,345	2,520	2,710	2,705	2,855
Vermiculite (free world) [18]—do	228	236	244	253	268	298
Mineral fuels:						
Coal (all grades) thousand metric tons	2,227,090	2,519,027	2,632,860	2,482,217	2,549,271	2,652,310
Anthracite—do	145,010	175,700	176,700	174,200	179,800	183,500
Bituminous—do	1,521,055	1,725,979	1,817,497	1,645,706	1,684,257	1,746,645
Lignite—do	561,025	617,348	638,663	662,311	685,214	722,165
Coke, metallurgical—do	246,311	260,456	279,616	272,049	273,126	284,257
Coke, other types [20]—do	46,888	45,760	46,090	45,060	45,730	45,470
Fuel briquets—do	105,300	104,600	108,300	113,100	118,500	121,700
Peat—do	78,150	169,700	162,100	159,600	163,000	163,000
Petroleum, crude thousand 42-gallon barrels	5,962,624	7,144,860	7,689,851	8,183,963	8,882,218	9,535,434

[1] Excludes Argentina, Austria, Finland, and United Kingdom.
[2] Excludes Bulgaria.
[3] Excludes North Viet-Nam.
[4] Excludes, Uganda.
[5] Excludes Czechoslovakia, Hungary, Iran, Kenya, and Malaya.
[6] Excludes a negligible amount produced in the Republic of the Congo.
[7] Excludes a negligible amount produced in Bulgaria, North Korea, Rumania, South-West Africa, and Spain.
[8] Excludes a negligible amount produced in Bulgaria, Mozambique, Panama, and Turkey.
[9] Excludes Brazil and U.S.S.R.
[10] Data not available.
[11] Incomplete total, represents only countries for which data is available.
[12] Excludes a negligible amount produced in Czechoslovakia, Eritrea, North Korea, and Rumania.
[13] Excludes Hungary and Rumania.
[14] Excludes China, Republic of Korea, and Rumania.
[15] Excludes a negligible amount produced in Ecuador and Korea.
[16] Excludes a negligible amount produced in Jamaica, Japan, Sarawak, Somali Republic, and Tanganyika.
[17] Excludes Mexico and U.S.S.R.
[18] Excludes Brazil.
[19] Excludes West Germany.
[20] Excludes a negligible amount produced in Canada.

NOTE.—Statistical tabulations with minor exceptions are based on data available prior to August 1, 1964.

Table 7 groups these distribution data in a different way, to show the proportion of 1963 output of seven major minerals produced in the industrialized countries on the one hand, and the less industrialized countries on the other. In this table the industrialized countries include the United States and Canada, free Europe, Oceania and Japan, South Africa, and the U.S.S.R. and European Communist countries;

Digitized by Google

the less industrialized countries include the rest of the world. A significant point of the table is the very large proportion of total output of these minerals accounted for by the industrialized countries themselves, despite their growing need for additional supplies from the less industrialized countries.

The rapid growth of mineral output has required large investment in both mineral extraction and mineral processing facilities. Statistical data for mineral investments on a worldwide basis are fragmentary at best, but the available evidence indicates that in recent years free world petroleum investments have averaged about US$10,700 million per year, while investments in the iron and steel industries of the three major industrialized areas (the United States, Western Europe, and Japan) appear to have ranged around US$3,000 million annually in the past 5 years. Data for other mineral investments are too scanty to permit even rough estimates for the major areas. Investment in steel in the United Kingdom and European Coal and Steel Community (ECSC) is now (1964) tapering off. Data for Japan are lacking, but it has been estimated that about US$2,700 million was invested in the Japanese iron and steel industry during 1955–62.[8]

For petroleum, the most complete coverage of investment is contained in the annual estimates prepared by the Petroleum Department of the Chase Manhattan Bank. According to these estimates, expenditures of the free world petroleum industry for expansion, modernization, and replacement of property, plant, and equipment (including the cost of dry holes but excluding exploration expenses) have averaged a little less than US$10,800 million per year for the period 1958–62 inclusive. Of a total of US$11,100 million in 1962, 51 percent was investment in production, about 14 percent in transporation (pipelines and marine), about 13 percent in refineries, about 14 percent in marketing facilities, and about 6 percent in chemical plants.

These estimates may be compared with the United States Department of Commerce figures for petroleum in its estimates of annual U.S. company expenditures for plant and equipment abroad, 1960–64 inclusive. These data exclude investments in petrochemical plants which are classified as a manufacturing industry. Investments in mining and smelting cannot be broken down according to the specific minerals involved because of the problem of revealing individual company data.

As presented in table 11, the financial assistance extended by five international lending agencies for investment in the mineral industries generally covers the mineral industries through the metal stage, and in the case of the steel and aluminum industries through the finished products normally regarded as products of the primary industry; in the chemical industry petrochemicals are excluded. The amounts reported in the table are gross of participations but net of cancellations.

[1] Based on production data (including estimates) as presented in world production tables in commodity chapters of Volumes I and II. In some cases, revised figures have been incorporated in individual country chapters of Volume IV, thus percentages given here do not necessarily agree with totals of production based on data in individual country chapters. Regional divisions of total conform to those used in the Table of Contents of Volume IV, except as noted.

[2] As used here, Free Europe includes all countries listed under Europe except: Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Rumania, and the U.S.S.R.

[3] As used here, includes all Middle East and Asian countries except China (Mainland), Mongolia, North Korea, and North Viet-Nam.

[4] Distribution of free world output only; no estimate of production made for Communist countries except Yugoslavia.

[5] Production data not available but recorded distribution for other areas based on a world total which includes an estimate for this area.

[6] Does not apply; see footnote 4.

[7] Less than 0.1 percent.

[8] Production by China (mainland), Mongolia, North Korea, and North Viet-Nam unknown, no estimate included in world total on which percentage figures are based.

Source: U.S. Department of Commerce. Survey of Current Business. September 1962, October 1963

Of the nearly US$755 million of international financing for the iron and steel industry, US$214.5 million was invested in Japan, US$56.6 million in Spain, and US$29.5 million in Mexico. Other large items under this heading were US$66 million for iron ore mining in Mauritania and US$40.5 million for the same purpose in Liberia. The bulk of the US$136.89 million for aluminum consisted of a US$110 million loan for the Volta project in Ghana, equally divided between the Export-Import Bank and Agency for International Development (AID).

Total	390.5	25.74	49.3	351.09	619.84	1,436.47

[1] January 1, 1958–December 31, 1963 except for AID, data for which cover July 1, 1957–December 31, 1963 (U.S. fiscal years 1958–64); gross of participations and loans sold but net of cancellations.
[2] Value of financing arrangements in which IFC has participated, and not the amounts of financial assistance it has extended from its own resources.
[3] Excludes loans of less than $100,000.
[4] Includes iron ore mining and finished steel capacity.
[5] Includes US$18.4 million loan for development of railway and port facilities for export of Indian iron ore.
[6] Excludes loans for iron and steel in ECSC countries in order to avoid overlap with data appearing in Table 8.
[7] Excludes US$55 million participation taken over by AID.
[8] Includes supporting assistance loan of US$3.5 million to Bolivia for tin production.
[9] Includes production of ammonia and urea, salt, and soda ash, sodium carbonate, sodium sulfate, carbon black, sulfur, caustic soda-chlorine, refractory bricks, quarry equipment, and US$2 million for a mineral resources survey.

Press releases; Agency for International Development. Operations Report Data as of June 30, 1963. Operations Report Data as of December 31, 1963; Export-Import Bank. Report to the Congress for the Twelve Months Ended June 30, 1963. V. II. Report to the Congress for the Six Months Ended December 31, 1963.

U.S. Department of Commerce estimates the value of United States direct investments in mineral industries outside the United States. In 1962 the earnings of the mining and smelting sector were about 11 percent of the book value, and its income about 10 percent of book value; in the case of the petroleum industry, earnings were about 13.6 percent and income about 12.5 percent. The total of mineral investments was 42.7 percent of all United States direct investments abroad in 1962.

Among the principal trends in mineral production shown by the statistical data for the period 1959–63 were the decline of iron ore and nonferrous ore production in Western Europe, the steady rise in output of the same commodities in Eastern Europe, the expansion of the steel industry in practically all regions, the rapid growth of iron ore production in Western Africa, South America, and Canada, and the growth and development of bauxite output in Western Africa, the Caribbean, and Australia. In the nonmetals, the most notable changes were the rapid growth of Canadian output of elemental sulfur (ob-

Digitized by Google

tained from natural gas) and of potash. In the fuels, the outstanding developments were the continuing rapid growth of petroleum production resulting from expansion of Middle Eastern output and the development of African production in Algeria, Libya, and Nigeria; the growth of natural gas output in Canada; and the discovery of large natural gas deposits in Northern Europe (still in the development stage). Production of uranium oxide declined steadily, affected by cutbacks of demand not yet offset by nuclear power requirements.

The economic trend of major importance was the growth of mineral import demands in the expanding economies of Western Europe and Japan. A subsidiary trend was the growth in developing less industrialized countries of mineral consuming and fabricating industries, often stimulated by nationalist economic policies, which may foreshadow their increasing share in the consumption of total mineral output. A constant factor throughout the period was the existence of political instability in many mineral producing regions.

The rapid world expansion of the iron and steel industry has had much to do with the development of new mineral production. The industry is undergoing a far reaching technological evolution involving conversion to the oxygen, fuel injection, and other new processes. The industrialized areas are shifting the use of higher grade ores imported from the less industrialized countries. This not only develops new production and increases world mineral trade but also, for cost reasons, creates a tendency toward concentration of new plants in coastal regions accessible to sea transport, and toward a greater degree of beneficiation of ores at the mines, even in the case of the high-grade imported ores, in order to save transport costs. Technological developments tend, for technical reasons connected with the new oxygen processes, to increase the proportion of iron ore in total raw material consumption.

In the fuel sector, the principal technological development has been the rapid rise of petroleum and natural gas-based fertilizer and chemical industries. This has been accompanied by a trend, both for economic reasons and in order to meet nationalistic political pressures, toward market oriented refineries, often requiring design improvements to make smaller units more economical. A second technological development has been the adoption of techniques for transporting natural gas by tanker, making possible the marketing of petroleum derived and other gases produced in regions remote from potential markets. A third technological change has occurred in the field of nuclear power, where the development of very large reactor units (upward of 500 megawatts) and the standardization of designs has brought uranium-fueled nuclear power within competitive range of fossil fuels in some locations.[9]

In the field of the nonmetals, techniques have been devised for the transport of molten sulfur by tanker, a development analogous to the transport of gas by tanker.

Tables 13 through 28 show production of a number of major commodities for the years 1959–63, listing major world producers and total world output. Commodities covered include bauxite, aluminum, copper, iron ore, steel ingots and castings, lead, tin, zinc, cement, phosphate rock, potash, sulfur (two tables, one covering elemental sulfur, the other covering pyrites), coal, and crude oil.

Peru	50	182	198	167	177
Australia	96	111	97	112	116
Japan	85	89	96	104	107
China (mainland) [4]	50	70	80	90	90
Total	3,194	3,744	3,896	4,102	4,166
All others [6]	476	476	504	518	574
World total [4]	3,670	4,220	4,400	4,620	4,740

[1] Data presented conform with that given in world production table in commodity chapter, volume 1. In some cases, revised figures for individual countries have been incorporated in country chapters of volume IV.
[2] Mexico, with an output of 58,000 tons, ranked ninth, ahead of Peru and mainland China.
[3] Recoverable.
Estimate.
[4] Smelter output.
[6] Derived figure; difference between indicated world total and sum of output of individually listed producers.

TABLE 16.—Leading world producers of iron ore, iron ore concentrates, and iron ore agglomerates [1]

(Thousand metric tons)

Country	1959 [2]	1960 [3]	1961 [4]	1962 [4]	1963
U.S.S.R. [5]	94,015	105,857	117,633	128,102	136,800

Brazil	8,907	9,345	10,220	10,778	[7] 12,000
Venezuela	17,201	19,490	14,565	13,266	11,863
Chile	4,649	6,041	6,989	8,092	8,507
Malaya	3,821	5,731	6,842	6,612	7,381
Luxembourg	6,509	6,977	7,458	6,507	6,990
Liberia	2,689	3,051	3,251	3,607	6,557
Total	386,692	456,819	431,019	438,617	451,707
All others [10]	52,352	65,419	71,622	68,747	70,189
World total [7]	439,044	522,238	502,641	507,364	521,896

[1] Data presented conform with that given in world production table in commodity chapter, volume 1. In some cases, revised figures for individual countries have been incorporated in country chapters of volume IV.
[2] Spain, with 4,609,000 tons and Australia with 4,207,000 tons ranked 14th and 15th, respectively.
[3] Peru with 6,990,000 tons and Goa with 5,856,000 tons ranked 12th and 15th, respectively.
[4] Peru, with 8,737,000 tons in 1961 and 5,949,000 tons in 1962 ranked 12th and 15th in those years, respectively.
[5] Data represents concentrates containing approximately 60 percent iron.
[6] Includes byproduct ores.
[7] Estimate.
[8] Roughly equivalent to ore containing 50 percent iron.
[9] Excludes the output of Goa.
[10] Derived figure; difference between indicated world total and sum of output of individually listed producers.

TABLE 17.—Leading world producers of steel ingots and castings [1]

(Thousand metric tons)

Country	1959 [2]	1960 [2]	1961	1962	1963
United States [3]	84,772	90,066	88,917	89,201	99,119
U.S.S.R.	59,971	65,293	70,751	76,300	80,220
Germany, West (including Saar)	29,435	34,100	33,458	32,563	31,597
Japan	16,629	22,138	28,268	27,546	31,501
United Kingdom	20,511	24,695	22,441	20,820	22,881
France	15,075	17,152	17,428	17,240	17,557
China (mainland)	[4] 13,350	[4] 18,450	9,500	10,000	12,000
Italy	6,762	8,229	9,329	9,757	10,156
Poland	6,160	6,881	7,234	7,684	8,004
Czechoslovakia	6,136	6,768	7,043	7,639	7,598
Total	258,801	293,772	294,369	298,750	320,633
All others [5]	46,469	52,378	56,491	60,750	65,397
World total [5]	305,270	346,150	350,860	359,500	386,030

[1] Data presented conform with that given in world production table in commodity chapter, volume 1. In some cases, revised figures for individual countries have been incorporated in country chapters of volume IV.

[2] Belgium, with a 1959 output of 6,437,000 tons and a 1960 output of 7,188 tons ranked ninth in each of those years.

[3] Data from American Iron and Steel Institute. Excludes production of castings by companies that do not produce steel ingots.

[4] Claime figures. Data appear to be exaggerated by one fifth or more.

[5] Estimate.

[6] Derived figure; difference between indicated world total and sum of output of individually listed producers.

TABLE 18.—Leading world mine producers of lead [1]

(Lead content of ore, recoverable where indicated, thousand metric tons)

Country	1959 [2]	1960	1961	1962	1963
Australia	321	313	274	376	416

All others [7]	(5)	1,526	1,376	1,513	1,532	1,358
World total [3]	(5)	12,952	13,574	13,533	14,302	14,600

[1] Data presented conform with that given in world production table in commodity chapter, volume 1. In some cases, revised figures for individual countries have been incroporated in country chapters of volume IV.
[2] Estimate.
[3] Rumania, with an output of 197,000 tons in 1959, 175,000 tons in 1960, and 206,000 tons in 1961 ranked 10th.
[4] British Guiana, with an output of 275,000 tons ranked 10th, ahead of Gabon.
[5] Data not available.
[6] Excludes output of Goa.
[7] Derived figure; difference between indicated world total and sum of output of individually listed producers.

TABLE 20.—Leading world mine producers of tin [1]

(Tin content of ore, long tons)

Country	1959	1960 [2]	1961 [3]	1962 [3]	1963
Malaysia	37,525	51,979	56,028	58,603	59,947
China (mainland) [4]	26,000	28,000	30,000	28,000	28,000
Bolivia (exports)	23,811	19,407	20,408	21,492	22,752
U.S.S.R. [4]	15,000	16,000	17,000	17,000	20,000
Thailand	9,684	12,080	13,270	14,679	15,587

Nigeria	5,541	7,675	7,779	8,210	8,723
Congo, Republic of the (Leopoldville)	9,194	8,636	6,314	6,875	7,196
Australia	2,351	2,202	2,745	2,714	3,085
South Africa	1,273	1,276	1,430	1,408	1,530
Total	151,992	169,851	173,548	176,291	179,767
All others [6]	9,508	10,549	10,552	10,709	11,233
World total [5]	161,500	180,400	184,100	187,000	191,000

[1] Data presented conform with that given in world production table in commodity chapter, volume 1. In some cases, figures for individual countries have been incorporated in country chapters of volume IV.
[2] Brazilian output, estimated at 1,556 tons exceeded reported output of South Africa, ranking Brazil 10th.
[3] Output of Ruanda-Urundi (1,474 tons in 1961 and an estimated 1,440 tons in 1962) exceeded that of South Africa ranking Ruanda-Urundi 10th.
[4] Estimated smelter output.
[5] Estimate.
[6] Derived figure; difference between indicated world total and sum of output of individually listed producers.

Total	34,821	38,259	41,892	44,572	47,110
All other [7]	3,554	3,641	3,583	3,628	4,090
World total [5]	38,375	41,900	45,475	48,200	51,200

[1] Includes output of all major crude mineral sources of phosphate, including apatite, guano, and similar materials. Data presented conform with that given in world production table in commodity chapter, volume 1. In some cases, revised figures for individual countries have been incorporated in country chapters of volume IV.
[2] Brazil with an output of 1,006,000 tons ranked sixth; Algeria with an output of 572,000 tons ranked eighth.
[3] Brazil with an output of 880,000 tons ranked sixth; Algeria with an output of 563,000 tons ranked ninth.
[4] Brazil with an output of 659,000 tons in 1961 and 566,000 tons in 1962 ranked 7th and 10th respectively, in those years.
[5] Estimate.
[6] Includes a category of material described by the Russians as "sedimentary rock."
[7] Derived figure; difference between indicated world total and sum of output of individually listed producers.

TABLE 24.—Leading world producers of marketable potash [1]

(Thousand metric tons, K_2O equivalent)

Country	1959	1960	1961	1962	1963
United States	2,162	2,394	2,479	2,225	2,600

[2] Qatar, with an output of 61 million barrels in 1959 and 63 million barrels in 1960 ranked 12th and 14th, respectively, and Colombia, with an output of 54 million barrels in 1959 and 56 million barrels in 1960 ranked 13th and 15th, respectively, in the years noted.

[3] Qatar, with an output of 64 million barrels in 1961 and 68 million barrels in 1962 ranked 15th in each year.

[4] Estimate.

[5] Excluding output from Kuwait-Saudi Arabia Neutral Zone, which is listed separately.

[6] Derived figure; difference between indicated world total and sum of output of individually listed producers above.

TRENDS IN METAL CONSUMPTION AND TRADE

The continuing high level of world industrial production resulted in a substantial increase in the use of most mineral products in 1963. Consumption of aluminum rose about 8 percent, of copper about 5.5 percent, of iron ore substantially, that of lead about 4.5 percent, of zinc about 6 percent, of sulfur more than 6 percent, and of petroleum about 6 percent. Tin consumption increased only marginally.[10]

Iron ore consumption in the United States rose about 8 percent above 1962 levels, and steel consumption increased by 7 percent.[11] Increased consumption of both minerals also occurred in Japan and the United Kingdom, while consumption in the EEC remained at about the 1962 level. Estimates of the American Bureau of Metal Statistics, the International Lead and Zinc Study Group, and the International Tin Council for changes in consumption of the five major nonferrous metals indicate that aluminum consumption increased more rapidly during 1961–63 than consumption of any of the other four.

With rising consumption, stocks of major minerals in the hands of producers were drawn down in 1963, inventories of consumers tending to rise. Total copper stocks declined only slightly, a sharp decrease

Digitized by Google

in the United States being almost offset by a substantial rise elsewhere. Producers' stocks of refined lead rose slightly in Europe but were sharply reduced in the United States and elsewhere, while stocks of refined zinc in producers' hands were reduced by about 46 percent, with sharp reductions in both the United States and Europe. Stocks of tin metal (primary and secondary) outside government stockpiles were reduced by 4,500 tons. The buffer stock of the International Tin Council was again exhausted in the autumn of 1963.

In terms of value, readily available data, even for 1962, are incomplete but United Nations analyses covering the major categories of mineral exports give an idea of trends. The evidence indicates that world exports of metalliferous ores, metal scrap, metals, and mineral fuels, as an aggregate, maintained a steady ratio of about 21 to 22 percent of total world exports during 1958–62, keeping pace with the rapid expansion of world trade as a whole. The data do not cover the precious metals or the nonmetallic minerals, and include manufactured metals (for example, steel) but not fabricated metal products.

In the 5-year period this group of mineral exports increased by 22.6 percent in value, with mineral fuels showing a steady rise after 1959 and ores and metals showing a more erratic trend. The sharp rise to higher levels in all three categories beginning in 1960 is noteworthy. The mineral fuels accounted for roughly half the total value and appear to have accounted for approximately 10 percent of total world exports.

TABLE 31.—World exports of major classes of minerals, by value[1]

(Million U.S. dollars)

Class	1958	1959	1960	1961	1962
Metalliferous ores and metal scrap (SITC Revised, 28)	2,960	3,300	3,870	3,850	3,450
Metals[2] (SITC Revised, 67, 68 less 681)	8,660	9,390	11,430	11,240	11,330
Mineral fuels and related materials (SITC Section 3)	12,260	12,030	12,650	13,480	14,490
Totals	23,880	24,720	27,950	28,570	29,270
Total world exports	107,510	114,940	127,400	133,040	140,580
Percentage of world total	22	22	22	21	21

[1] United Nations Monthly Bulletin of Statistics. April 1964, Special Table B; March 1964, Special Table C.III.C. Categories used are those of the Standard Industrial Trade Classification (SITC).
[2] Excludes precious metals.

About two-thirds of total world exports of these commodities were taken by the three major free world industrialized areas. In 1962 North America took 17 percent of the total, Western Europe 45 percent, and Japan 4.6 percent. A significant trend has been the growing import share of Western Europe in the total; from 1959 to 1962 its import share of exports of metallic ores and scrap rose from 36 percent to 41 percent, of metals from 44 percent to 48 percent, and of mineral fuels from 40 percent to 44 percent. Japan's share similarly rose but at a much lower level. Concurrently there has been, proportionately, a shift of mineral exports from United States to European destinations, particularly marked in the case of Latin America; Western Europe's share of Latin American mineral exports rose from 20.7 percent to 25.3 percent in the period, and Japan's share from 0.3 percent to 2.5 percent.

The European Communist countries' exports of the group of mineral commodities have also grown rapidly, but are concentrated chiefly on destinations within the countries themselves. Its other principal trading partner, Western Europe, took only 19 percent of these mineral exports in 1962 as compared with 20 percent in 1958, and the increase in the value of Eastern Europe's mineral exports to Western Europe amounted to slightly less than US$200 million during the period.

UN data for 1962 trade, in the form of a network or matrix table, bring out the strong influence of transport costs and geographical proximity on trade flows of mineral commodities. They show the existence of a Europe-Africa-Middle East mineral trade area, a Japan-Far East-Pacific trade area, and a hemispheric North America-Latin America trade area. At the same time it shows both Japan and Europe reaching into Latin America for additional supplies, and data for previous years would show this trade increasing.

A high proportion of trade in the industrialized regions consists of intraregional trade; about 39 percent of North America's mineral imports originated in North America, and 49 percent of Western Europe's mineral trade originated in Western Europe. Much of this intraregional trade in the two areas consists of coal and metals, a large part of the latter probably products of the steel industry.

No data are available to show the proportion of total world trade by volume accounted for by mineral commodities, but evidence suggests that it is well over half the total tonnage of goods moving in international trade and probably growing as a percentage of the total. According to United Nations data, the tonnage of petroleum and petroleum products alone, which has risen consistently since 1956, in 1962 exceeded half the total of all seaborne international trade; to this of course would have to be added the millions of tons of other mineral commodities moving in international commerce.[12]

As compared with 1961, trade in major minerals in 1962 appears to have increased in volume by about 6 to 6.5 percent. Trade in iron ore was up by 6 percent, in coal and coke by 6 percent, and in crude petroleum by 8 percent. The level of nonferrous metal trade was practically unchanged, increased imports by the United States and Japan offsetting decreased takings by Western Europe.[13]

United Nations quantum indices of major mineral imports by chief industrial areas in 1961 and 1962 are shown in table 33.

TABLE 33.—Imports of major minerals[1] into selected industrialized countries

(Quantum index, preceding year=100)

Commodity	United States[2]		EEC countries[3]		United Kingdom		Japan[4]		Total[5]	
	1961	1962	1961	1962	1961	1962	1961	1962	1961	1962

[4] Based on 9 months' returns.
[5] Estimated on basis of partial returns indicated.

Source: United Nations Commodity Survey 1962.

Data permitting detailed examination of the patterns of international trade in minerals are readily available only for iron ore, steel products, bauxite, solid fuels, crude petroleum, and lead and zinc ores and concentrates. All relate to 1962 trade except those for lead and zinc ores and concentrates, which summarize 1963 trade.

In general, these tables are self-explanatory, but some comment on sources of data may be desirable. The tables for bauxite and iron ore were prepared by the Bureau of Mines. The table for steel products is a rearrangement of the data appearing in the United Nations' Economic Commission for Europe (ECE) study, Statistics of World Trade in Steel 1962, and the definitions, nomenclature, and other qualifications are as given in that document.

The tables of lead and zinc ores and concentrates, based on International Lead and Zinc Study Group data and relating to 1963, should be used with caution. In the cases of both metals they are

Digitized by Google

based on partial data, and the data for Belgium-Luxembourg among the importers are for gross weight of ore rather than metal content, thus distorting the comparability of the figures. Even with these limitations, however, both tables tend to confirm the description of trade patterns given in this chapter.

The tables for solid fuels and crude petroleum are similar to that for steel in that they are rearrangements of data appearing in the United Nations study, World Energy Supplies 1959–62, and are subject to the qualifications of that document; it is important to note, with respect to the petroleum table, that Libya is classified as part of the Middle East and not as part of Africa. In all tables relying on United Nations data the quantities may differ somewhat from data appearing in other sources but the general pattern of trade shown by them will not significantly differ from the picture given by other sources if allowance is made for treatment of Libya, in the petroleum table, as part of the Middle East.

With respect to the table on steel products, the point of importance is the high proportion of the total imports in most geographic regions accounted for by intraregional trade in steel; in Western Europe 91 percent, in the European Communist countries 60 percent, and in the Far East and Oceania 37 percent and 32 percent, respectively, of total imports of steel was accounted for by intraregional trade in 1962. By contrast, only 16 percent of North American steel trade consisted of intraregional trade.

In crude petroleum the dominance of the less industrialized regions as exporters, and of the industrialized areas as importers, is clear; while in solid fuels the import status of Western Europe and the Far East (that is, Japan) and the diminance of North America (the United States) and Eastern Europe as exporters is plain. In contrast to crude petroleum, however, the solid fuel table shows a high proportion of total imports in the major industrial regions consisting of intraregional trade.

A flow chart, figure 1, adapted from one prepared by the Copper Division, Business and Defense Services Administration, U.S. Department of Commerce, exhibits graphically the major flows of 1962 trade in copper.[14] Statistical data on which the copper trade flow chart is based, converted from short tons as reported in the source, are given in table 41. The data do not cover all exports but only those of the seven major exporting countries, and the import data do not include all imports of the importing countries. The export data for Northern Rhodesia and the Republic of the Congo are partly estimated.

Data for world trade in 1963 are still incomplete but available information suggests that both the value and the volume of trade in minerals increased substantially with respect to that of 1962. According to preliminary United Nations indexes of volume, trade in solid fuels was up about 14 percent, in crude petroleum about 12 percent, and in aluminum about 12 percent. Trade in the nonferrous metals as a group remained at about the 1962 level, increases in aluminum and tin offsetting decreases in copper, lead, and zinc.

Trade in iron ore (another large item) also expanded substantially, with United Kingdom, Japanese, and EEC imports (from outside the Community), rising sharply, while United States imports remained at 1962 levels.

In terms of value as well as of quantity, however, solid fuels and crude petroleum evidently accounted for the bulk of the increase in world mineral trade in 1963.

TRANSPORTATION

Transportation costs are a key factor in the economic structure of the world's mineral industries, and changes in costs and available facilities play a large role in shaping the flow of mineral trade. The two forms of transport which affect the mineral industries significantly are maritime transport and pipelines.

Rapid changes have been occurring in both transport sectors. In the case of maritime transport these involve the sharply increasing sizes of both dry cargo and tanker vessels, the rapidly growing fleet of bulk carriers designed for ore or ore-oil carriage, and the development of specialized tankers for the transport of liquefied gas and molten sulfur. In pipelines, the principal development is the construction of international crude and products pipelines in Europe to serve the growing markets there, and the expansion of crude pipeline facilities from the North African fields. A second development, just beginning, is the construction of international gas pipelines to market the Netherlands and North European natural gas discovered in the last 3 years.

The world's merchant fleet at the end of 1963 comprised over 18,000 vessels with a total deadweight tonnage of 194.3 million tons, an increase of 5 percent over 1962. Of this total, 3,436 with a deadweight tonnage of 74 million tons consisted of tankers (including whaling tankers), and 1,726 with a deadweight tonnage of 23.8 million tons consisted of bulk carriers. In recent years both bulk carriers and tankers have increased their share of the total in terms of tonnage; in 1961 bulk carriers accounted for 9 percent of the total and tankers for 37 percent; in 1962 bulk carriers accounted for 11 percent and tankers for 38 percent; while in 1963 the bulk carrier percentage rose to 12 percent and tankers remained at 38 percent. Bulk carrier tonnage increased by 25 percent in 1962 and by 20 percent in 1963. After a rapid rise in the late fifties, tanker tonnage as a percentage of the total appears to have been relatively stable in the past 3 years.[15]

Moreover, the size of both bulk carriers and tankers has been growing, limited primarily by harbor depths and terminal facilities at ports. In 1962 more than 40 percent by tonnage of the world's dry

cargo fleet was 10,000 gross registered tons (GRT) or over, 16 percent 20,000 GRT or over, and 8 percent 25,000 GRT or over, in the same year 24 percent of the tanker fleet was 40,000 GRT or over, and 83 percent by tonnage of new tankers on order were 45,000 GRT or over. The decreasing per ton cost of transport as size of vessels goes up explains the growing size of vessels.

The seaborne trade in minerals is divided into three fairly separate trades—the ore trade, the petroleum trade, and the coal trade. Typically, the petroleum trade has long been handled by company-owned tankers supplemented by time chartering of other tankers in the market as needed, while in the past both the ore trade and the coal trade were handled primarily by the chartering of vessels (frequently on a voyage basis) in the open market. The ore trade practice is rapidly shifting and a steadily increasing volume of the total is now handled either by industry-owned ore carriers or by other bulk carriers chartered by the industries on long term. United States, British, and Japanese steel companies or industries possess their own fleets, as do some of the U.S. aluminum companies. The coal trade, on the other hand, still relies on chartering in the open market.[16]

Both bulk carriers and tankers can be diverted to the grain trade, the other principal bulk cargo, though the ordinary tramp freighters with which they compete in that trade cannot economically be shifted to the ore and oil trades. This possibility affects the structure of freight rates and causes a tendency for rates in different trades to move together.

In both the tanker and dry cargo trades the increasing size, efficiency, and specialization of new ships tend to make older and smaller vessels uneconomic, and a situation thus arises in which at the same time a statistical surplus of tonnage exists and large new tonnages are coming off the ways, with an inevitable effect on freight rates.

In the summer of 1963 the International Tanker Owners Association, then representing an estimated 54 percent of the tanker tonnage expected to come on the free market by the end of the year, devised a scheme to encourage the laying-up of nonprofitable vessels in order to stabilize rates. Japanese and American owners did not participate. The scheme was to go into effect on September 10, 1963.[17] At mid-1964 it was reported that the scheme had probably had some effect; lead-up tonnage was stabilized at a level somewhat under 1 million tons, though the usual seasonal decline occurred in the winter of 1963–64. All except one of the laid-up tankers were said to be under 25,000 tons, and in the spring of 1964 some 2.5 million tons of smaller tankers were reported to have been shifted to the grain trade.[18]

Requirements for tankers were said also to be affected by the development of North African fields as a source of crude petroleum for European markets, and by the construction of pipelines from the European Mediterranean coast to interior refineries and markets, which are discussed briefly later. The shortening of the tanker hauls resulting from this tends to reduce the demand for sea transport.[19]

Nevertheless, continuing high levels of industrial output and import demand in the main industrialized regions of the world, plus the extraordinary demands for grains and fuels due to crop failures and the adverse winter of 1962–63, pushed most ocean freight rates upward during the year. Table 43 shows UN-published indexes for dry cargo and tanker rates based on Danish, West German, Netherlands, Norwegian, and British indexes.

Pipeline developments of major importance to the international mineral trade in 1963 included the expansion of Algerian and Libyan pipeline facilities and the completion, at the end of 1962, of one major line (the South European pipeline) from Marseilles to the Strasbourg-Karlsruhe area on the upper Rhine River. Plans exist to extend this to Ingolstadt in southern West Germany. Other lines are under construction or in the planning stage; one from Genoa to Ingolstadt via Ulm, with a possible extension to Munich, and a second from the head of the Adriatic to Vienna, for which at least two separate proposals have been made.[20]

A second petroleum pipeline project of great potential importance is the so-called COMECON or Druzba pipeline from the Soviet Urals-Volga area to the Communist countries of Eastern Europe. Designed to link this region with refineries in Poland, East Germany, Hungary, and Czechoslovakia, the pipeline was also planned to include extensions to the Baltic ports of Klaipeda and Ventspils and possibly to

Odessa on the Black Sea. According to the (U.S.) National Petroleum Council, the section from Brody (in the western U.S.S.R.) to Uzhgorod on the Hungarian border and Bratislava in Czechoslovakia was completed in late 1961, and work on the main 1,350 kilometer segment from Kuibyshev to Mozyr' was to begin in 1962.[21] According to another report, the entire COMECON pipeline is to be completed by the third quarter of 1964, presumably excluding the Baltic extensions, on which work is said to have been indefinitely suspended at the end of 1960. The same report indicates that in the view of the chairman of the Soviet export agency the line when completed will not be sufficient to meet the expected demands of the countries.[22]

Finally, a significant transport development of somewhat lesser importance was the completion of the canalization of the Moselle River in Germany and France, which opened a channel for barges up to 1,350 tons in size to the Lorraine steel complex in France. This is expected to reduce transport costs for coal and ore, and partially remove the transport handicaps under which that portion of the French steel industry has worked.[23]

PRICES

The United Nations 1963 overall export price indexes for minerals showed little change from 1962 levels, and in the case of metallic ores showed a decline.

The experience of the developed and underdeveloped areas differed, however, as shown in table 45.

Despite the small changes in the yearly averages there were steady upward pressures on the prices of most internationally trade minerals during the course of the year which, in most cases, began to take effect from midyear on. Of the nonferrous metals, prices of aluminum, lead, zinc, and tin rose during the year and copper prices began to rise at the very end of the year. Prices of nickel, bauxite, and petroleum remained at about 1962 levels. Prices of iron ore and the additive minerals, particularly manganese and chrome, were generally lower. Coal prices averaged the highest since 1957.[24]

[2] Excludes precious metals.

Copper prices in the United States were stable at US$0.306 per pound throughout the year, and were supported at the level of £234 per long ton on the London Metal Exchange in the first half by producers, who in the latter part of the year sold at the same level as demand rose, in order to stabilize the price. In December 1963 the price on that exchange began moving upwards, averaging £235.900 for the month.

Aluminum prices were held steady by producers at US$0.225 per pound in New York and £180 per long ton in London until October, when they were raised to US$0.23 and £184, respectively.

Lead and zinc prices fluctuated more but their rises began earlier, in February and March in London and at midyear in New York. Prices of lead in London rose from an average of £54.3 per long ton in January to an average of £74.4 in December; the corresponding rise for zinc was from £67.7 to £94.9 per long ton. In New York lead prices rose from US$0.103 in January to US$0.125 in December, while zinc rose from US$0.115 to US$0.13.

Tin prices , dominated by the continuing shortfall of new production, U.S. stockpile releases, and International Tin Council efforts to stabilize them within the agreement range, shot upward in the last quarter as the Council's buffer stock was exhausted. From a January average of £852.046 per long ton in London the price rose steadily until May, receded slightly in the summer, and rose to an average of £1,010.950 in December.

Conscious efforts by producers to control traditionally fluctuating nonferrous metal prices were significant in the case of copper, and it was clear that their price policies were dominated by competitive considerations. Copper producers had adopted voluntary output restrictions in 1962, and large African producers had been supporting prices on the London Metal Exchange at £234 per ton; in the latter part of 1963 they appeared as sellers at this price in the face of upward trends and did not permit the price to rise until aluminum producers, their principal competitors for power transmission cable, had raised their prices. Lead and zinc producers made no effort to stabilize price levels but it began to be evident that they were unhappy about the sharp 1963 rises; reporting to shareholders in the spring of 1964, the chairmen of both Rio Tinto-Zinc and New Broken Hill Consolidated expressed fears of consumer substitution of other materials, and the former ex-

758-002—65——4

Digitized by Google

pressed the hope that the U.S. Government would consider stockpile releases of both metals, as had been requested by lead-zinc producers and consumers in the United States.[25]

At issue, the question appeared to be the role of the London Metal Exchange in the metal markets of the world. The major metal market outside the United States, it has dominated the formation of nonferrous metal prices for most of the world, and both producers and consumers have relied on its quotations for the pricing of contracts. Moreover, it has been freer in many respects than most other markets, since U.S. metal prices are affected by both tariffs and quotas. The Metal Exchange itself has in the past year attempted to broaden its role by introducing a "Continental" contract and authorizing Rotterdam as a delivery point; and it has also had under consideration the introduction of trading in aluminum. Efforts of producers to stabilize prices appeared to some observers as a possible threat to the future role of the Exchange, and some seemed to believe that a dual-price structure was here to stay, at least in the case of copper.[26]

GOVERNMENT POLICIES AND PROGRAMS

In this section, only selected aspects of some policies or programs of a multilateral character and U.S. Government policies and programs with effects on international mineral production and trade are reviewed. Readers interested in the mineral policies and programs of specific countries should refer to the appropriate country chapters of this volume (or, for those of the U.S. Government, to volumes 1 and 2 of the Minerals Yearbook) for a discussion of them.

The only international commodity agreement applying to a mineral product is the International Tin Agreement. Twenty-one Governments representing producing and consuming countries (Australia, Austria, Belgium, Bolivia, Canada, Republic of the Congo, Denmark, France, India, Indonesia, Italy, Japan, Republic of Korea, Malaysia, Mexico, Netherlands, Federation of Nigeria, Spain, Thailand, Turkey, and the United Kingdom) are members. The United States is not a member but consults with the Council on matters of common interest. The primary object of the agreement is to stabilize tin prices through the operation of a buffer stock managed by a buffer stock manager under the direction of the International Tin Council, the executive body established by the Agreement. Floor and ceiling prices are established by the Council; at the floor price the buffer stock manager must buy, at the ceiling price he must sell, and in an intermediate range designated the "middle sector" he neither buys nor sells.

During 1963 operating within the limits of floor and ceiling prices (then £790 and £965) the buffer stock manager was compelled to sell out the entire stock in a vain effort to halt price rises, notwithstanding the sale of substantial quantities of tin from U.S. Government stockpile in the same period. Upon exhaustion of the Council's stock at the end of the third quarter the price shot upward as noted earlier.

Digitized by Google

Throughout the year the Council had constantly under consideration the question of U.S. Government stockpile disposals, which had been going on under Congressional authorization since 1962. At the Council's third meeting of the year in October it decided to ask the U.S. Government to confer in Washington at a mutually convenient early date with a representative mission from the Council in order to obtain an understanding between the Council and the U.S. Government concerning plans for future disposals of tin. This meeting occurred about the end of November.

At its fourth meeting of the year in December the Tin Council revised the price range upward, the floor price becoming £850 and the ceiling price £1,000, with the middle sector becoming £900 to £950 per long ton.[27]

During 1963 U.S. stockpile authorities began developing long-range plans for disposals of a number of commodities in accordance with the recommendations of an interagency committee approved by the President on January 30, 1963. Among these recommendations was one proposing "that the goal of long-term disposals should be the sale of surplus materials in amounts which can be absorbed by regular marketing channels without avoidable loss to the Government and without creating hardships in the domestic or friendly foreign economies, and that plans should be established on an individual commodity basis in amounts and over periods of time which will not unduly interfere with production and employment."[28] It is planned that consultations with appropriate industries, foreign governments, and Government agencies will accompany the development of major disposal plans so that interested groups will have an opportunity to express their views.

U.S. import quotas for lead and zinc were unchanged in 1963. Petroleum import quotas were modified so that quotas for imports of crude oil and products into areas east of the Rocky Mountains are based on a percentage of estimated crude and natural gas liquid production during the quota period instead of on a percentage of past production. This modification does not apply to residual fuels.

One other major policy problem of an international character was not resolved during 1963 but there were significant developments with respect to it. This is the effort of the six countries of the European Economic Community to develop a common energy policy. The question is fully reviewed in the 12th annual report of the European Coal and Steel Community High Authority.[29]

In 1957 the High Authority of the Coal and Steel Community and the executives of the EEC and Euratom had been charged with pursuing long-term energy studies, presenting periodic reports to the High Authority and the Governments, and submitting to the Council of Ministers proposals for energy policy. In 1962 (April 5), the Ministers asked the executives to prepare proposals for a common energy policy. They submitted two memoranda on the subject in that

year, one (June 25, 1962) on energy, policy and one (December 21, 1962) on long-term energy perspectives. The energy policy memorandum proposed the establishment of a common energy policy in two stages: in the first stage reliance would be placed on national measures, and in the second on Community institutions. The Ministers asked the High Authority to study the legal implications of this and to suggest the changes that might be necessary in the basic agreements of the EEC, European Coal and Steel Community, and Euratom.

On April 10, 1963 the High Authority submitted to the Ministers a "draft agreement for creating conditions permitting the realization of a common market in energy." In its annual report the High Authority described this text as "flexible enough to meet any criticism inspired by the same principles as the memorandum"; that is, the energy memorandum of June 1962.

On March 21, 1963 the Council of Ministers discussed the long-term energy study and appointed a working group to study it. On May 2, 1963, it noted submission of the draft agreement, and decided to have the energy memorandum examined by a special energy policy committee whose work would proceed parallel with that of the working group, which was directed to report to it. The special committee was to be composed of high officials designated by member states, and representatives of the High Authority, the European Economic Community Commission, and the Euratom Commission. The draft agreement was referred to it on June 6, 1963. Its report was to be submitted before October 31, 1963.

The High Authority in its annual report described the working group's report as containing "a solid nucleus of common opinions" regarding energy, in general agreeing with the energy study. It notes, however, that before the special committee could consider it, the Council referred to it a proposal of the West German Government for a "transitional protocol" which in effect would authorize subsidies to the coal industry without regard to the provisions of the Coal-Steel Community agreement. The special committee had to consider this and the working group's report together; as a consequence it had to concentrate on economic questions and had no time to consider the juridical aspects. At the end of the special committee's study, the representatives of governments serving on it drafted a resolution which was transmitted to the Council of Ministers on November 22, 1963.

The Council considered this on December 2, 1963, and failed to reach unanimous agreement. Representatives of the High Authority, the EEC Commission, and the Euratom Commission were present. The High Authority's annual report indicates that the three executives considered the resolution "clearly insufficient to realize a common energy policy."

The High Authority enumerated five conditions which it declared must be met for the proposal to obtain its support: First the common energy policy must go into effect beginning January 1, 1970; second the draft resolution constitutes a "first step" toward the application of principles enunciated in the interexecutive memorandum; third the High Authority's conception of a common energy policy is set forth in the memorandum and confirmed by the draft agreement; fourth grants

Digitized by Google

of subsidies must be subordinated to the prior authorization of the High Authority; and fifth it is important to establish special measures for coke.

Being unable to decide, the Council remanded the draft resolution to the special committee with the other documents, with instructions to report before the March 1964 session of the Council.

The core of the differences between the draft agreement and the draft resolution, of which the texts are printed in the High Authority's report, appears to be mainly in the enunciations of their objects.[30] The draft agreement, in its article 2, enunciates its objects as one to assure consumers a free choice of energy sources, two to promote lower prices, insofar as consistent with stability, three to insure safety and regularity of supplies, four to facilitate development of research in all forms of energy, five to avoid unnecessary protective measures, and six to facilitate the adaptation of industry to the evolution of energy supplies. The draft resolution, on the other hand, would have as its objects the "realization of conditions assuring economically reasonable exploitation of sources of energy by avoiding distortions among producers susceptible of disturbing the common market," and the promotion of the development of energy production within the Community; it also calls for aids and subsidies to coal, promotion of community oil production, and a common inventory or stock policy.

The High Authority in its annual report noted that at the time of writing it was preparing another initiative on the subject.

Finally, another problem of multilateral character is foreshadowed by the discovery of large deposits of natural gas near the North Sea coasts of the Netherlands and Germany, and the subsequent explorations of offshore areas in the North Sea itself for petroleum- and/or gas-bearing strata. All drilling so far has been confined to territorial waters, but late in 1963 the U.K. Government enacted legislation empowering it to claim areas of the continental shelf sea-bottom and license concessions therein, under the terms of the 1958 Geneva Convention regarding the subsurface resources of the continental shelf.[31] No move has yet been made by any government to bring about a parceling out of jurisdictional claims to the North Sea Continental Shelf, but presumably all with territories bordering that sea will eventually put forward claims.

[30] The draft agreement also provides for necessary changes in the three Community agreements, to which the draft resolution does not address itself.

The Mineral Industry of Canada

By Lester G. Morrell [1]

AGAIN in 1963, as in nearly every year since 1946, the Canadian mineral industry has established a new national record in value of mineral production. The 1963 estimated total value of $2,976 million is 5 percent higher than the 1962 value of $2,845 million.[2] As in previous years, metals made up more than half the value of total production. For selected years since 1949 the category percentages and total value are as follows:

Year	Metals (percent)	Nonmetals and structural (percent)	Mineral fuels (percent)	Total value (millions)
1950	59.0	21.8	19.2	$1,045
1955	56.1	20.8	23.1	1,795
1960	56.4	20.9	22.7	2,493
1961	53.7	21.0	25.3	2,582
1962	52.6	20.0	27.4	2,845
1963 [1]	50.6	19.7	29.7	2,976

[1] Estimate.

Crude petroleum, Canada's most valuable mineral product, accounted for 21 percent of the total value of minerals in 1963. In descending order came nickel 12 percent, iron ore 10 percent, copper 10 percent, gold 5 percent, and uranium 5 percent. Asbestos accounted for 5 percent, sand and gravel 4 percent, and cement 4 percent. The complete list of Canada's mineral products includes more than 50 basic commodities.

All regional areas showed production increases except the Northwest Territory which declined $3 million, and Ontario which fell $36.7 million below the 1962 output. The greatest gain was $68.5 million in Alberta where an increase of $48.7 million is credited to crude petroleum and $20.4 million to natural gas byproducts. Quebec and Maritime Provinces accounted, collectively, for 25 percent of the 1963 total value of mineral products. Ontario again was the largest with 29 percent; the three prairie provinces (Manitoba, Saskatchewan, and Alberta) totaled 36 percent, and British Columbia and the two territories (Yukon and Northwest) made up 10 percent.

[2] Values are in Canadian dollars. Since May 1962 the Canadian dollar has been held at 92.5 cents in relation to the U.S. dollar.

Digitized by Google

The role of minerals in the Canadian national economy in 1963 is recorded by the Dominion Bureau of Statistics mine production index of 300, compared with the 1949 base index of 100, and per capita mineral output of $159, compared with $153 in 1962 and $75 in 1950. Of the 1963 officially estimated $32.8 billion net national income (at factor cost), and $43.0 billion gross national product, minerals and primary mineral products contributed, respectively, 9.6 percent and 6.9 percent.

Of the 6.7 million national labor force, approximately 3 to 4 percent are employed in the mineral industry, compared with about 9 percent in agriculture. Of the national total $21.8 billion paid in 1963 in wages and salaries, the mining industry drew $584 million whereas the combined pay of agriculture, fishing, trapping, and forestry employees totaled $553 million. Federal income taxes paid by the mining, quarrying, mineral processing, metallurgical, metals fabricating, and mineral fuels industries accounted for one-fifth of the income tax paid by all of Canada's industries.

On the international scene, the total value of mineral production in 1963 ranks Canada sixth after the United States, the U.S.S.R., Venezuela, China, and West Germany. With continuation of growth virtually assured, Canada's mineral industry will surpass that of West Germany in 1964 or 1965 and thereafter will occupy fifth place. Fuels make up the major portion of mineral products in Venezuela and China. Canada is the third largest producer of metals and with the expected expansion in potash and sulfur Canada's output of industrial minerals will also be the world's third largest. Each of 14 Canadian mineral products furnish more than 10 percent of the world supply of those products. The following mineral products, in percentages (1962 data) are included: Aluminum (smelter) 11; asbestos 40; cobalt [3] 11; columbium-tantalum [3] 12; gypsum 10; nickel 59; platinum metals 38; selenium [3] 24; silver 13; sulfur (elemental) 17; tellurium [3] 15; titanium (ilmenite) [3] 13; uranium oxide [3] 25; and zinc 13. Canada's greatest mineral production potential is in nonferrous metals, total value of which was estimated at US$1,119 million, compared with US$1,300 million for the United States in 1963. Thus, if the recent trend of new discoveries and developments continues and production is not economically curtailed, Canada soon will surpass the United States in value of nonferrous metals production. The Department of Mines and Technical Surveys has predicted [4] that 1964 Canadian mine and smelter output of nonferrous metals will account for, respectively, 12 and 9 percent of world totals.

More exhaustive accounts of 1963 developments in minerals exploration as well as many phases of mining technology and milling and process metallurgy have been summarized in journal articles.[5]

GOVERNMENT POLICIES AND PROGRAMS

The year 1963 has recorded steady advance in resource and technological developments by both government and industry. In the field of exploration, copper and zinc prospects in Newfoundland, gold in the Val d'Or and Malartic regions of Quebec, and the copper and molybdenite deposits of British Columbia received major attention. Geophysical methods were extensively applied, with airborne electromagnetic devices and ground surveys using Induced Polarization (IP) as the principal tools for metallic deposits and seismic equipment for petroleum and gas structures. Of particular interest to earth scientists was the completion during 1963 of three holes totaling 10,089 feet drilled in the Muskox Intrusive as part of Canada's contribution to the International Upper Mantle Project in the Northwest Territories.

The broadest economic benefit to Canadian mining in recent years has been the stabilizing in May 1962 of the Canadian dollar at 92.5 cents in relation to the U.S. dollar. This had the effect of increasing the value of virtually all mineral products exported not only to the United States but also to all dollar-trading countries. The higher price thus attained stimulated exploration throughout Canada, particularly in gold areas. Despite curtailments in base-metals production under voluntary quota limitations, three new copper-zinc mines and a new electroyltic zinc refinery came into production in 1963. Other important industrial developments of the year include the start of production of iron ore pellets and asbestos in Newfoundland and the beginning of construction on a zinc smelter in New Brunswick. In western Canada, 1963 marked the first full year of potash production, a noteworthy expansion in output of petroleum as well as in production and international sales of sulfur.

Of particular interest to investors and new operators, was an updated review of Federal taxation and legislation applicable to the mineral industry.[6]

SOURCE MATERIAL

Production and trade statistics presented in this review are from Dominion Bureau of Statistics (DBS) summary reports, compiled in each instance with the appropriate agency such as Department of Mines and Technical Surveys or the Department of Trade and Commerce. The latest year's estimates of mineral production are regularly published early in January as Preliminary Estimate of Canada's Mineral Production, DBS catalog No. 26–202. Trade statistics are based primarily on annual total figures given in the December issues of Trade of Canada—Exports by Commodities and Trade of Canada—Imports by Commodities, DBS catalog Nos. 65–004 and 65–007, respectively.

Text material is derived from numerous sources. Official materials include reports of the Federal Department of Mines and Tech-

nical Surveys, Department of Northern Affairs and National Resources, published reports of the counterpart Provincial agencies, and industry journals.

PRODUCTION

Although the total value of Canada's minerals established an alltime record in 1963, the year's output of many individual commodities particularly metals was below the quantity levels of 1962. Voluntary cutbacks by principal producers of nickel, lead, zinc, and copper and the loss of markets for uranium accounted in large measure for the downward trend in metals output. Among the nonmetals, the general uptrend in both quantity and value has continued. Small declines were recorded in barite, feldspar, magnesite, pyrite, and a few others, but these were overshadowed by notable gains in sulfur, gypsum, and potash. In the fuels section, 1963 production of each of the four major categories exceeded the 1962 records in both quantity and value. Greatest gains were in crude petroleum and natural gas and their refined products.

Cut [13]—do	156	182	158	182	[6] 180
Sulfur [14]—do	806	909	841	1,106	[6] 1,700
Talc, soapstone, and pyrophyllite—do	35,540	37,771	43,650	41,876	49,569
Mineral fuels:					
Coal:					
Bituminous—do	7,874	8,020	7,429	7,283	7,894
Lignite—do	1,767	1,969	2,004	2,047	1,700
Coke:					
High temperature—do	3,715	3,513	3,538	3,648	3,883
Low temperature [11]—do	50	40	35	10	
Fuel briquets—do	139	74	61	49	66
Natural gas—million cubic feet	417,335	522,972	657,892	946,909	1,116,217
Peat moss—thousand tons	167	168	203	216	235
Petroleum:					
Crude—thousand 42-gallon barrels	184,778	189,534	220,861	244,132	258,435
Refinery products:					
Gasoline, total—do	98,252	102,724	104,654	111,239	119,608
Kerosine and jet fuels—do	18,121	19,833	22,364	24,433	26,289
Distillate fuel oil—do	74,413	75,511	77,085	82,215	94,325
Residual fuel oil—do	37,354	35,387	37,349	41,071	44,889
Lubricants—do	1,993	2,121	2,164	1,699	1,837
Other products—do	21,128	27,535	35,705	29,942	23,606
Refinery fuel and loss—do	18,563	17,448	18,497	19,532	20,960
Total—do	269,824	280,559	297,818	310,131	331,514

[1] Antimony content of antimonial lead alloys, flue dust, and dore slag.
[2] Refined metal and bullion plus recoverable bismuth content of concentrates exported.
[3] Refined metal from domestic ores plus cadmium content of some exported ores and concentrates.
[4] All forms, excludes the cobalt in nickel-oxide sinter shipped to United Kingdom by International Nickel Co., but includes the cobalt in Falconbridge nickel-copper matte to Norway.
[5] U.S. imports, from production preceding 1955.
[6] Final figure: supersedes figure given in commodity chapter, volume I.
[7] Data for 1961–63 not strictly comparable with earlier years.
[8] Refined nickel and nickel in produced oxide and recoverable nickel in matte exported.
[9] Cement sold or used by producers.
[10] Value of clays including bentonite and value of products from common, stoneware, fire clay and other types of clay.
[11] Estimate.
[12] Spodumene concentrates.
[13] Building, ornamental, paving and similar uses of granite, limestone, marble, slate, and sandstone.
[14] Includes sulfur from natural gas and from pyrite, pyrrhotite, and smelting of sulfide ores.

TRADE

Approximately 15 percent of Canada's gross national product during the 1960–63 period has been accounted for by exports. Minerals and metal exports (including mineral fuels) comprised one-third of the total, whereas the combined value of agriculture, forest, and fishery products made up half; manufactured goods made up the remaining

Digitized by Google

sixth. In 1963 the value of exported minerals and metals was estimated at $2.0 billion (two-thirds of the total output), compared with $1.9 billion in 1962. The commodity breakdown for exports in 1961, 1962, and 1963 was as follows:

Commodity [1]	Millions			Percent of total (1963)
	1961	1962	1963 [2]	
Iron	$226.7	$220.5	$260.0	13.0
Aluminum	246.1	288.1	307.0	15.3
Copper	193.7	202.6	210.0	10.5
Lead	27.6	25.8	23.0	1.2
Nickel	343.0	323.9	336.0	16.8
Zinc	58.7	60.6	57.0	2.8
Uranium oxide	192.7	166.0	150.0	7.5
Asbestos	131.3	135.6	131.0	6.6
Fuels	204.9	314.2	347.0	17.3
Others	133.2	198.1	179.0	9.0
Total	1,757.9	1,935.4	2,000.0	100.0

[1] Metals include content of ores, concentrates, and primary metal products. Fuels include coal, oil, and gas.
[2] Estimate based on 10-month data.

The destination of Canada's 1963 mineral exports, in percentage of total mineral exports was as follows (1962 data in parentheses): United States 61 (63), United Kingdom 19 (17), European Economic Community 5 (7), European Free Trade Association 4 (4), Japan 5 (4), and others 6 (6).

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963
Metals:				
Aluminum:				
Alumina, Al content	17,124	3,514	2,399	United States 2,354; New Zealand 75.
Scrap	26,701	27,438	39,504	Italy 17,655; United States 12,984.
Pigs, ingots, wire bars, etc	441,828	522,723	576,228	United States 249,017; United Kingdom 152,823.
Bars, rods, sheets, castings	20,837	20,541	11,600	India 2,366; United States 2,035; Mexico 1,781.
Foil	133	420	422	United Kingdom 279; New Zealand 75.
Fabricated materials, n.e.s.[1]	10,557	7,155	12,975	Mexico 3,496; New Zealand 2,498.
Antimony, in antimonial lead	541	718	(3)	(3).
Bismuth	177	173	(3)	(3).
Cadmium	903	1,062	880	United Kingdom 593; United States 266.
Calcium kilograms	50,213	56,291	41,776	United States 11,839; West Germany 8,754.
Cobalt:				
Metal	274	246	335	United States 253; United Kingdom 67.
Oxides and salts, gross weight	690	739	498	United Kingdom 494.
Columbium concentrate kilograms	16,137	684,892	(3)	(3).
Copper:				
Ore and matte, metal content	38,913	86,676	84,304	Japan 52,004; Norway 13,845.
Scrap, slag, sludge	7,334	7,545	8,693	Japan 5,766; Spain 1,591.
Refinery shapes	241,534	202,341	195,032	United Kingdom 89,541; United States 67,220.
Semimanufactures:				
Bars, rods, shapes, etc	19,181	20,105	23,922	Norway 7,047; Switzerland 4,285.
Pipe and tubing	5,960	4,982	6,818	United States 2,209; New Zealand 1,611.
Wire and cable	6,715	415	341	Italy 108; Saudi Arabia 24.

See footnotes at end of table.

TABLE 2.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963
Metals—Continued				
Iron and steel:				
Iron ore—thousand tons	15,107	21,993	24,238	United States 18,623; Japan 2,011.
Pig iron—do	599	459	437	United States 348; Italy 51.
Ferroalloys:				
Ferrochrome	1,490	5,989	2,640	United States 2,494.
Ferromanganese	216	123	9	All to Columbia.
Other (type not specified).	45,116	42,254	(2)	(2).
Steel:				
Ingots and equivalent primary forms—thousand tons	296	240	341	United States 235; United Kingdom 106.
Semimanufactures—do	414	439	(2)	(2).
Lead:				
Ore and concentrate, metal content.	64,380	53,973	48,766	United States 24,587; Belgium-Luxembourg 11,758.
Pigs, blocks, and shot	106,718	114,125	88,127	United Kingdom 39,988; Japan 8,193.
Alloys, scrap, and metal, n.e.s.[1]	2,678	3,788	4,393	United States 3,791; Italy 484.
Magnesium	5,470	5,961	(2)	(2).
Nickel:				
Ore, matte, and speiss, metal content.	84,311	70,225	75,651	United Kingdom 42,475; Norway 30,434.
Oxide, metal content	16,349	10,088	13,796	United Kingdom 2,092; United States 8,554.
Ingots and other refined forms.	121,112	110,415	99,024	United States 85,333; United Kingdom 6,782.
Scrap and fabricated	3,147	4,064	4,508	United States 4,069; United Kingdom 95.
Platinum-group metals:				
Ore and concentrate, metal content.	troy ounces 626,876	542,985	506,782	United Kingdom 479,838; Norway 19,444.
Metals—do	4,619	28,262	42,845	Japan 31,499; United States 9,424.
Selenium metal and salts, selenium content.	kilograms 156,852	147,690	202,168	United States 104,418; United Kingdom 86,138.
Silver:				
Ore and concentrate, metal content.	thou. troy ounces 10,353	8,801	8,287	United States 6,793; West Germany 530.
Refined metal	thou. troy ounces 10,783	9,445	10,835	United States 10,768; Brazil 61.
Titanium slag, 70 percent TiO_2	115,323	98,423	(2)	(2).
Uranium, U_3O_8[3]	8,741	8,385	6,946	United States 4,893; United Kingdom 2,046.
Zinc:				
Ore and concentrate, metal content.	180,821	219,955	193,272	Belgium-Luxembourg 13,044; Norway 11,825.
Blocks, pigs, slabs	188,940	191,167	181,441	United Kingdom 75,166; United States 67,359.
Alloys, scrap, dross, etc	3,216	4,982	5,191	United States 2,732; Belgium-Luxembourg 1,937.
Fabricated materials, n.e.s.[1]	452	424	1,195	United States 505; United Kingdom 457.
Nonmetals:				
Abrasives:				
Fused alumina, crude and grains.	120,946	149,567	138,309	United States 124,259; United Kingdom 14,047.
Silicon carbide, crude and grains.	76,500	56,940	66,138	United States 62,478; United Kingdom 2,688.
Asbestos:				
Crude	160	165	177	West Germany 98; Japan 40.
Milled fibre, thousand tons—all grades.	1,013	1,056	1,094	United States 565; West Germany 75.
Barite, crude	155,759	209,471	145,051	United States 127,270; Trinidad 14,225.
Bentonite, earths and clays[3]	4,085	2,999	2,817	All to United States.
Cement, Portland	226,230	198,821	247,481	All to United States.
Clay and clay products: value, thousands	$5,778	$7,543	$6,874	(2).
Feldspar	2,382	3,355	2,977	All to United States.
Fluorspar	1,858	4	2,732	United States 2,728.
Gypsum, crude—thousand tons	3,465	3,777	4,267	All to United States.
Lime	28,301	64,939	88,980	United States 86,808.
Limestone, crude, crushed, and refuse.	(2)	804,850	743,410	United States 743,275.

See footnotes at end of table.

TABLE 2.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963
Nonmetals—Continued				
Nepheline syenite	176,535	175,683	184,398	United States 167,397; United Kingdom 10,464.
Potash materials [3]	(2)	70,786	512,358	United States imports only.
Salt [4]	513,000	724,000	672,000	United States 637,000.
Sand and gravel	353,342	321,244	323,074	United States 323,071.
Silica, quartzite	24,289	141,706	43,034	All to United States.
Sodium sulfate	78,968	67,176	59,283	All to United States.
Stone, cut value, thousands (granite, marble, slate, and others).	$288	$352	$370	(1).
Sulfur, crude and refined	197,644	362,901	744,742	United States 484,669; U.S.S.R. 53,715.
Talc and soapstone [3]	1,709	1,952	1,905	United States imports only.
Mineral fuels:				
Coal, bituminous	852,147	810,945	956,501	Japan 700,769; United States 249,256.
Coke, all types	205,660	143,230	140,009	United States 135,997.
Natural gas—million cubic feet	168,180	319,566	340,953	All to United States.
Petroleum:				
Crude thousand 42-gallon barrels.	65,223	91,590	90,876	All to United States.
Refinery products:				
Gasoline, total—do	570	964	481	United States 477; St. Pierre 4.
Distillate fuel oil—do	314	413	529	United States 181; France 157.
Residual fuel oil—do	730	1,646	1,599	Mainly to United States.
Lubricants—do	2	33	65	Australia 37; United States 25.
Other—do	1,930	2,164	1,882	(1).

[1] Not elsewhere specified (n.e.s.).
[2] Data not available.
[3] Data given are from United States Import Statistics.
[4] Estimate.

TABLE 3.—Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal sources, 1963
Metals:				
Aluminum:				
Bauxite and alumina	2,008,089	1,825,766	1,831,959	British Guiana 672,839; Surinam 500,034.
Cryolite	3,660	4,636	4,406	Denmark 3,382; United States 536.
Semiman- value, thousands ufactured products.	$8,406	$16,019	$23,305	(1).
Fully manufactured do products.	$19,862	$23,872	$21,743	(1).
Antimony:				
Regulus, metal content	377	579	470	Mainland China 393; Yugoslavia 30.
Oxide and salts, metal content.	183	299	306	United Kingdom 232; United States 49.
Bismuth: Metal, residues, and salts (metal content).	15	31	6	United Kingdom 3; Bolivia 2.
Chromium, chromite	64,653	65,289	45,045	Philippines 16,561; Rhodesia and Nyasaland 12,820; United States 12,620.
Cobalt oxides, gross kilograms weight.	12,866	18,568	12,833	United Kingdom 11,927; United States 906.
Columbium metal alloys—do	2	635	(4)	(1).
Copper:				
Scrap	3,591	412	2,952	United States 2,942; British Guiana 10.
Blocks, pigs, ingots	3	133	5,941	United Kingdom 3,517; Belgium-Luxembourg 594.
Bars, rods, sheet, tubing, etc.	2,072	1,242	1,519	United States 1,369; West Germany 75.
Wire	1,777	1,827	20	United States 15; United Kingdom 5.
Oxide and sulfate	441	526	578	United Kingdom 340; United States 233.

TABLE 3.—Imports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal sources, 1963
Metals—Continued				
Iron and steel:				
Iron ore——thousand tons	4,199	4,224	4,909	United States 4,588; Brazil 3,179.
Pig iron	313	9,168	16,133	Finland 15,260; United States 873.
Ferroalloys:				
Ferromanganese	10,996	13,595	20,538	Republic of South Africa 16,952; Japan 2,374.
Silicomanganese	1,971	2,473	2,136	United States 1,418; Japan 370.
Ferromolybdenum	96	60	(1)	(1).
Ferrotungsten	235	130	283	United Kingdom 234; Sweden 34.
Steel:				
Ingots and equivalent primary forms.	5,976	6,506	3,828	United States 3,146; United Kingdom 541.
Semimanufactures	600,601	551,526	(1)	(1).
Lead:				
Pigs, blocks, bars, and sheets	1,074	586	1,668	Mexico 1,045; United States 511.
Litharge	464	700	984	Mexico 452; United States 348.
Manganese ore	68,960	82,304	96,970	Ghana 41,221; Republic of the Congo (Léopoldville) 21,747; Brazil 18,719.
Mercury——76-pound flasks	4,117	3,224	5,889	Spain 3,041; Italy 1,725.
Molybdenum molybdic oxide	121	149	117	All from France.
Nickel, unwrought and semifabricated including alloys.	3,905	3,799	9,954	Norway 8,085; United States 1,830.
Silver——thousand troy ounces	12,278	15,182	7,950	United States 7,348; Mexico 535.
Tantalum metals and alloys.	kilograms 1,074	146	(1)	(1).
Tin, blocks, pigs, long tons and bars.	3,525	2,274	4,193	Malaya 3,044; United Kingdom 550.
Titanium dioxide	24,150	11,449	3,055	United Kingdom 1,719; United States 1,336.
Tungsten, scheelite ore	228	1,295	293	Korea 201; Argentina 91.
Zinc:				
Scrap and dross	115	313	212	All from United States.
Pigs, slabs, blocks, anodes	699	644	580	Do.
Bars, plates, sheets	788	694	715	United States 492; Belgium-Luxembourg 114.
Dust and granules	784	806	1,062	United States 447; Belgium-Luxembourg 380.
Chemicals	3,597	4,042	3,739	United Kingdom 2,217; United States 1,055.
Nonmetals:				
Barite, ground	1,714	2,201	3,474	United States 3,404; West Germany 70.
Bentonite, clay and drilling mud	12,903	13,566	(1)	(1).
Cement, all types	26,505	24,062	28,409	United Kingdom 10,996; Belgium-Luxembourg 5,069.
Clays and value, thousands clay products.	$47,112	$48,264	$49,640	(1).
Diamonds:				
Unset——thousand carats	56	62	63	Belgium-Luxembourg 31; Israel 17.
Bort for drilling——do	1,084	1,130	1,123	United States 894; United Kingdom 149.
Feldspar	1,561	1,725	2,359	All from United States.
Fluorspar	29,727	61,550	60,598	Mexico 44,042; Republic of South Africa 8,694.
Gypsum, crude	59,942	63,455	67,702	Mexico 66,497; United States 1,199.
Lime	34,884	32,762	40,180	United States 40,016.
Limestone, crushed, ground, broken, etc.	717,109	664,055	680,677	All from United States.
Magnesium compounds:				
Magnesia, dead burned	19,907	22,546	14,830	United States 10,384; Yugoslavia 2,000.
Magnesia, calcined	2,573	2,461	2,081	United States 1,988.
Magnesium chemicals	5,136	5,257	14,491	United States 11,663; West Germany 2,554.
Mica, unmanufactured	669	1,046	788	United States 704; India 71.
Phosphate rock——thousand tons	958	1,049	1,177	United States 1,149; Morocco 21.
Phosphate fertilizers, total	180,282	169,498	137,781	All from United States.
Potash products:				
Fertilizers	182,738	161,202	88,664	United States 50,919; France 17,341.
Chemicals and compounds	8,924	8,402	(1)	(1).
Salt	180,860	233,017	301,710	United States 142,923; Mexico 90,049.
Sand and gravel——thousand tons	1,205	761	510	All from United States.
Silica sand	628,857	694,395	714,104	United States 710,871.

See footnote at end of table.

TABLE 3.—Imports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal sources, 1963
Nonmetals—Continued				
Sodium sulfate, and Glauber's salt.	30,127	28,824	17,688	United States 11,884; United Kingdom 5,496.
Stone, cut value, thousands (granite, marble, slate, and other).	$3,339	$3,579	$3,299	(1).
Sulfur, elemental	298,967	176,981	136,655	United States 136,602.
Talc	18,330	21,907	24,983	United States 23,894.
Mineral fuels:				
Coal:				
Anthracite—thousand tons	960	829	769	United States 750; United Kingdom 19.
Bituminous—do	10,204	10,614	11,361	United States 11,360.
Coke, all types—do	594	531	548	All from United States.
Natural gas—million of cu. ft.	5,574	5,575	6,877	Do.
Petroleum:				
Crude thousand 42-gal. bbl.	133,249	134,518	147,721	Venezuela 90,085; Near East 54,003.
Refinery products:				
Gasoline, total—do	2,021	1,846	2,882	Netherlands Antilles 794; United States 677.
Kerosine and jet fuel—do	2,764	2,475	2,351	Netherlands Antilles 1,219; Venezuela 732.

COMMODITY REVIEW

METALS

Aluminum.—Bauxite and alumina from Canadian-owned mines and plants in British Guiana and Jamaica were the principal raw material base for the Canadian aluminum industry's record production of 1963. The bulk of this was produced by the extensive facilities of Aluminum Company of Canada, Ltd.—Alcan. The Canadian British Aluminium Co. smelter at Baie Comeau, Quebec, is supplied with alumina from Reynolds Metals Co. in Texas and the Fria consortium in Guinea. Chryslum, Ltd., an affiliate of the Chrysler Corp., has leased the Alcan Beauharnois plant since 1959 for production of special alloys.

Location and annual capacity of alumina and aluminum facilities at the beginning of 1963 are summarized as follows:

	Metric tons
Alumina plants:	
Alcan:	
Kirkvine, Jamaica	**500,000**
Ewarton, Jamaica	**277,000**
Mackenzie, British Guiana	**300,000**
Arvida, Quebec, Canada	**1,152,000**
Aluminum reduction plants:	
Alcan:	
Arvida, Quebec	**338,000**
Shawinigan, Quebec	**64,000**
Isle Maligne, Quebec	**104,000**
Kitimat, British Columbia	**174,000**
CBA, Baie Comeau, Quebec	**91,000**
Chryslum, Beauharnois, Quebec	**34,000**

Digitized by Google

During 1963, the Jamaica and British Guiana alumina plants were operating at full capacity, with the excess above Canadian requirements going to European smelters. The Arvida, Quebec, alumina plant was operated at about 50 percent capacity. Aluminum reduction plants averaged 80 percent of national capacity.

Developments in Canada's aluminum industry in 1963 were confined to expansion of manufacturing facilities. The new cold-rolling mill opened in June will add 23,000 metric tons to bring the total annual capacity of the Kingston, Ontario, Alcan plant to 50,000 tons of sheet and rolled products. The Reynolds companies in Quebec have announced plans to add a cold mill, a foil mill, and an annealing furnace to the Cap de la Madeleine plant and the new 23,000-ton capacity rodmill will be built at Murray Bay.

Copper.—Canada's 1963 mine production and refinery output of copper were both slightly lower than in 1962. Voluntary curtailment by the principal producers (5 percent by Noranda Mines, Ltd.; 5 percent by Gaspé Copper Mines, Ltd.; 13 percent by The International Nickel Co., Inc.; and 17 percent by Falconbridge Nickel Mines) was the principal cause of the decrease. No production was recorded in 1963 from the Territories, following the suspension of mining at the North Rankin Nickel Mines, Ltd., and the Dominion Explorers, Ltd., Kathleen Lake mine. Three new names were added to the already long list of Canadian copper producers. Mattagami Lake Mines, Ltd., New Hosco Mines, Ltd., and Orchan Mines, Ltd., all in the Mattagami Lake area of northwest Quebec, commenced production in 1963. The copper and zinc concentrates produced in the two new mills (3,000 tons of ore per day at Mattagami Lake Mines, Ltd. and 1,900 tons of ore per day, at Orchan Mines, Ltd., which includes 900 tons of ore per day from New Hosco, will be shipped to the Noranda smelter. The Consolidated Mining & Smelting Co. of Canada, Ltd. (Cominco) Wedge mine and the Heath Steele Mines, Ltd., which initiated New Brunswick as a copper producer in 1962, accounted for 7,394 metric tons of copper in concentrates for shipment to Japan in 1963.

In addition to the 39 mine producers of copper listed in 1963 several more are expected to join the ranks of producers in 1964 and 1965.

Exports of copper in 1963 were approximately at the same level as in 1962, the bulk of the raw material exports going to Japan, refined metals to United Kingdom, and manufactured products to more than 50 countries. Domestic consumption of refined copper by Canadian industries in 1963 appears to be a record 154,000 metric tons, compared with 137,460 tons in 1962.

Gold.—Despite the highest price (averaging $37.74 per troy ounce) paid by the Royal Canadian Mint since 1950, the recorded total production of gold in 1963 was the lowest in 15 years. During this period, however, annual output has been relatively steady, fluctuating only between 3.97 and 4.62 million ounces. Two small mines were closed, and a few small gold mines reported production for the first time in 1963. Of the 50 lode gold mines producing in 1963, 42 received assistance under the Emergency Gold Mining Assistance Act. This act, initiated in 1948 and subsequently altered and renewed several times, has again been further extended through 1967. In 1962, the most

758-002—65——5

Digitized by Google

recent year for which data are available, payments under the Assistance Act were about $14.5 million.

Following a long established pattern, approximately 55 percent of the 1963 gold output came from auriferous-quartz mines in Ontario. Eighty-three percent of the national total was from auriferous-quartz mines, and about 15 percent (two-thirds of which came from Quebec) was coproduced with base metals. Slightly less than 2 percent of the Canadian gold was from alluvial deposits of which the majority (6 dredges and 35 small placer operations) were in the Yukon Territory.

Iron Ore, Pig Iron, and Steel.—Production of iron ore in 1963 was a record-high Canadian output—12 percent above the previous peak established in 1962. Each of the four producing provinces also showed an increase in 1963. Newfoundland accounted for 8.5 million metric tons, Quebec for 10.7 million tons, Ontario for 6.7 million tons and British Columbia for 1.9 million tons.

Recent improvement in facilities and expansion of existing mines and ore processing plants not only increased the nation's iron ore production capacity but also provided for better grade products. Total annual production capacity of the 15 companies that comprised the Canadian iron ore mining industry in 1963 exceeded 38 million metric tons. The principal development during 1963 was the addition of pelletizing facilities at three plants. The largest of these, built near Labrador City adjacent to the Iron Ore Co. of Canada concentrator by the Carol Pellet Co. is rated at 5 million tons of pellets per year. Smaller pelletizing plants of 540,000 and 750,000 tons annual capacity respectively were built by Lowphos Ore., Ltd., near Capreol, Ontario, and by the International Nickel Company of Canada, Ltd. (Inco) (to treat roasted pyrrhotite concentrates), near Sudbury, Ontario. These are initial steps in announced plans that will raise the national pelletizing capacity from 1.5 million tons annually in 1962 to over 14.0 million tons in 1965.

Exports of iron ore in 1963 were the highest on record, totaling 24.2 million metric tons. Approximately 77 percent of these exports went to the United States, 10 percent to United Kingdom, and 8 percent, all from British Columbia mines, to Japan. A total of about 5 percent went to European Common Market countries. Consumption of iron ore from domestic sources by the Canadian iron and steel industry was at an alltime high as indicated by the following Dominion Bureau of Statistics summary of Canadian iron ore charged in Canadian blast furnaces:

	Thousand metric tons			
	1960	1961	1962	1963
Crude iron ore:				
From domestic mines	1,364	859	831	697
Imported	1,890	1,886	1,646	1,618
Sinter, pellets, etc.:				
From domestic mines	932	1,230	1,345	1,831
Imported	697	1,621	2,198	2,778
From own processing [1]	1,496	1,561	1,627	1,535
Total	6,379	7,157	7,647	8,459

[1] Domestic and imported materials processed in plants located at iron and steel plants.

Digitized by Google

Imports of iron ore, over 93 percent of which came from the United States, also were at a record high level of 5.4 million tons in 1963.

The Canadian iron and steel industry is comprised of four integrated companies: The Steel Co. of Canada, Ltd. (STELCO), Hamilton, Ontario; Algoma Steel Corp., Ltd. (ALGOMA), Sault Ste. Marie, Ontario; Dominion Foundries and Steel, Ltd. (DOFASCO), Hamilton, Ontario; and Dominion Steel and Coal Corp., Ltd. (DOSCO), Sydney, Nova Scotia. Three companies make pig iron but do not have steel-making facilities: Quebec Iron & Titanium Corp. (QIT), Sorel, Quebec; Canadian Furnace Division of Algoma Steel Corp., Ltd., Fort Colborne, Ontario; and Consolidated Mining & Smelting Co. of Canada, Ltd. (Cominco), Kimberley, British Columbia. In addition about 35 smaller plants produce steel from scrap in electric furnaces, and 11 plants make ferroalloys. In 1963, 18 rolling mills were in service; 3 in Nova Scotia, 4 in Quebec, 7 in Ontario, and 1 in each of the four western provinces.

Canadian iron and steel making capacity has been increased about 25 percent in the 1960–63 period. As of December 1963, pig iron annual capacity [1] in Canada was rated at 5,266,100 metric tons. Steel furnace capacity at the same time totaled 7,541,750 tons; distributed to open-hearth ingots 4,537,700 tons; electric and oxygen ingots 2,561,900 tons; and castings 442,150 tons. Principal products made in 1962 and 1963 include the following, in thousand metric tons:

	1962	1963
Pig iron	4,798	5,366
Ferroalloys	125	130
Steel ingots	6,396	7,316
Steel castings	111	114
Rolled products:		
Carbon steel:		
Hot rolled	5,017	5,725
Cold rolled, and coated	2,048	2,265
Alloy steel	155	187
Total rolled products	7,220	8,177

Lead and Zinc.—While 1963 mine output of both lead and zinc were below the 1962 output, refined zinc production in 1963 was the highest on record. Refined lead production, though slightly greater than in 1963, was below the levels of both 1960 and 1961.

Twenty-seven mines supplied the lead and zinc ores mined in Canada in 1962–63. By far the greatest production was from the Sullivan mine of Cominco in British Columbia. All of Canada's refined lead is produced in the Cominco smelter at Trail, British Columbia. Three companies operate electrolytic zinc refineries to produce refined zinc: Cominco (175,000 metric tons annual capacity), the Hudson Bay Mining & Smelting Co., Ltd. (72,000 tons capacity), at Flin Flon on the Manitoba-Saskatchewan border, and the new 66,000-ton-capacity plant of Canadian Electrolytic Zinc, Ltd., which commenced production of slab zinc in September 1963, at Valleyfield, 30 miles west of Montreal, Quebec.

[1] Sixteen blast furnaces and one electric reduction furnace. Additional capacity of about 300,000 metric tons is also available for electric smelting ilmenite.

Digitized by Google

Exports of lead and zinc in 1963 were substantially lower than in the previous year. However, the pattern of exports remained the same. The bulk of ore and concentrate exports of both metals were shipped to the United States, and the United Kingdom was the principal destination of refined lead and zinc. Domestic consumption of lead, 71,000 metric tons in 1963, was slightly higher than in 1962. Consumption of refined zinc 71,950 tons in 1963 was 12 percent above the 1962 level.

Under the stimulus of rising metal prices, lead from 10.0 to 12.5 Can. cents and zinc from 10.5 to 13.0 Can. cents between the beginning and end of the year, prospecting, mine development, and other lead-zinc industrial activities in 1963 have been at a relatively high level. Important events of the year included the startup of the Canadian Electrolytic Zinc, Ltd. plant at Valleyfield, Quebec, and the beginning of construction of the new lead-zinc smelter at Balladune Point, New Brunswick. In Quebec's Mattagami Lake area, Orchan Mines, Ltd., and Mattagami Lake Mines, Ltd., began mining zinc-copper ores at respectively 2,700 and 900 tons per day. In November the Kam-Kotia Porcupine Mines, Ltd., near Timmins, Ontario, started by-product zinc shipments from its copper mining operation. Acquisition of the old Britannia copper-zinc mine, north of Vancouver, British Columbia, by the Anaconda Company (Canada), Ltd., was effected early in the year, and on Great Slave Lake, in the Northwest Territories, extensive preparations at Pine Point continued through the year. When completed, probably in 1966, this Cominco operation is expected to ship about 200,000 tons of lead and zinc concentrates to the company's smelter at Trail in southern British Columbia.

Molybdenum.—Production of molybdenum in 1963 was the highest to date. The increase of 22 percent over the previous years' output was in part due to the byproduct recovery of molybdenite at Murdochville, Quebec, by Gaspé Copper Mines, Ltd. The bulk of Canada's 1963 production, as in previous years, was from the Molybdenite Corp. of Canada, Ltd. mine near La Corne, Quebec. In response to the strong demand for molybdenum, particularly in Japan and Western Europe, several new molybdenite prospects were being developed during the year in Quebec and British Columbia. Of these, the Preissac Molybdenite Mines, Ltd., near Cadillac, Quebec, and the Bethlehem Copper Corp., Ltd. near Ashcroft, British Columbia, were expected to commence production early in 1964.

Known deposits of molybdenum in Canada are said to be capable of raising Canadian annual production to over 6,800 metric tons of molybdenum. Domestic consumption however is small, and expansion would be subject to export market conditions.

Nickel.—The Canadian nickel industry is based on 7 companies operating 15 mines, 11 mills with a combined daily milling capacity of 67,000 metric tons of nickel-copper ores, 4 smelters, 2 refineries in Canada, and 1 refinery in Norway. Output, valued at $363 million in 1963 was down slightly from 1962. The decrease to about 93 percent of national capacity was a controlled reduction of output to avoid stock surplus. The two principal Sudbury District producers, Falconbridge Nickel Mines, Ltd., and International Nickel Co., of Canada, Ltd., both effected modest cutbacks in production in October. Sherritt

Digitized by Google

Gordon Mines, Ltd., mined slightly lower grade ore but maintained capacity tonnage at its Lynn Lake, Manitoba, mine. The several small-scale producers of nickel ores and concentrates were not affected by the cutback. The Gordon Lake, Ontario, mine and 500-ton-per-day mill which commenced operation in 1962 was acquired late in 1963 by Metal Mines Ltd., a subsidiary of Canadian Faraday Corp., Ltd. Concentrates were shipped to the Inco smelter at Copper Cliff. The new mine of Marbridge Mines, Ltd., in northwestern Quebec, which initiated Quebec production of nickel in 1962, operated at near its 400-ton-per-day milling capacity and produced 2,355 tons of nickel in concentrates in 1963. Giant Nickel Mines, Ltd., near Hope, British Columbia, produced concentrates containing 1,677 tons of nickel for export to Japan.

Platinum-Group Metals.—Production of platinum-group metals in 1963 was almost 25 percent less than the annual average of 457,556 troy ounces for the previous 3 years. In 1963, and possibly in earlier years the U.S.S.R. probably replaced Canada as the leading world producer. Platinum normally comprises 46 percent of the platinum-group metals produced in Canada. Palladium, with small amounts of rhodium, ruthenium, and iridium make up the remaining 54 percent. Aside from a few ounces of platinum metals obtained in some past years from placer gravel deposits in the Yukon and British Columbia, the entire Canadian output is recovered as a byproduct of nickel-copper sulfide ores mined in the Sudbury District of Ontario and since 1961 at the Thompson mine in northern Manitoba. On a national basis the original ore is said to carry 0.02 to 0.03 ounce of platinum metals per ton. Recovery is effected only by Inco and Falconbridge. In addition to ores from their own mines, both companies treat a small quantity of purchased ore. The platinum content is not recovered from nickel-copper materials treated at the Fort Saskatchewan refinery of Sherritt-Gordon Mines, Ltd.

Facilities for producing refined platinum or platinum-group metals are not available in Canada. The platinum metals recovered as sludges from the nickel electrolytic tanks by Inco are exported to the precious metals refinery of the Mond Nickel Co., Ltd., at Acton, England. Nickel-copper matte, containing platinum metals is exported by Falconbridge to the company's electrolytic nickel refinery in Norway. The platiniferous residues from the refinery treatment are sent back to the Englehard Industries, Inc., precious metals refinery at Newark, N.J. A portion of the Canadian platinum that is refined in the United Kingdom and the United States is returned and exported from Canada to world markets.

Silver.—Silver production in Canada is all coproduced with or as a byproduct of ores of other metals. Accordingly, the national output of 1963 was a 5-year low, reflecting voluntary cutback in production at several large nickel-copper, copper, and lead-zinc operations. Nevertheless, with exceptionally high world prices for silver, the Canadian price ranged from $1.31 to $1.40 per ounce throughout the year, and the total value of about $41.3 million was an alltime high for Canadian silver. In 1962–63, 28 [8] Canadian producers of silver are listed. Geo-

[8] Exclusive of numerous small producers who ship argentiferous ores or concentrates to customs mills or smelters.

Digitized by Google

graphically, Ontario accounted for 32 percent, Yukon 20 percent, British Columbia 21 percent, and Quebec 16 percent of the total silver produced in 1963. By sources, according to 1962 analysis, base metal ores yielded nearly 86 percent; the silver-cobalt mines of Ontario produced 12 percent and gold ores, both lode and placer, 2 percent. The great bulk of Canada's silver is exported. In 1963, the United States received nearly 92 percent of Canada's exports. Of the total exports about 43.3 percent was contained in ores and concentrates, and 56.7 percent was as bullion. The refined silver is produced in Canada by Cominco (6,847,606 ounces in 1963), Canadian Copper Refiners, Ltd., Cobalt Refinery, Ltd., The Royal Canadian Mint, Hudson Bay Mining & Smelting Co., Ltd., and the Hollinger Consolidated Gold Mines, Ltd.

Consumption of silver in Canada was primarily for coinage. Approximately 14 million ounces was used for this purpose in 1963, compared with less than 11 million ounces in 1962 and 5 million in 1961. Manufacturers of silverware, photographic materials, and other products absorbed 4.8 million ounces in 1962.

Uranium.—In 1963, production of uranium oxide (U_3O_8) continued the scheduled decline that will adjust Canadian deliveries to about 1,000 metric tons annually by 1970. The 1963 output was obtained from eight mines, two of which were closed by the yearend. Approximately 76 percent of the year's output was from Ontario's four mines at Elliot Lake (Denison, Milliken, Nordic, and Stanrock) and two mines in the Bancroft area (Faraday and Bicroft), and the remaining 24 percent was from the Eldorado Mining and Refining, Ltd., and Gunnar Mining, Ltd., in northern Saskatchewan. Under existing contracts, deliveries for the years 1964–71 to U.S. Atomic Energy Commission (USAEC), United Kingdom Atomic Energy Authority (UKAEA) and the Canadian Government stockpile, are scheduled as follows, in metric tons U_3O_8:

Year	USAEC	UKAEA	Stockpile	Total
1964	1,634	3,894	1,769	7,297
1965	554	2,076	----------	2,630
1966	416	1,489	----------	1,905
1967	----------	1,112	----------	1,112
1968	----------	1,089	----------	1,089
1969	----------	1,089	----------	1,089
1970	----------	1,089	----------	1,089
1971	----------	846	----------	846

Reserve estimates of ores of radioactive materials in Canada were officially revised during 1963. As of December 31, measured, indicated and inferred reserves of uranium ore were estimated to total 236 million metric tons, averaging 0.124 percent U_3O_8. This is equivalent to a recoverable reserve of 222,000 metric tons U_3O_8. In addition, substantial quantities of thoria (ThO_2) are associated with the uranium ores of Elliot Lake and Bancroft areas in Ontario. Free world reserves of recoverable uranium and thorium, as compiled by the Mineral Resources Division, Department of Mines and Technical Surveys, are as follows, in metric tons:

Digitized by Google

Country	U_3O_8	$Th O_2$
Australia	7,700	45,400
Brazil	450	34,100
Canada	222,000	145,000
France	22,200	[1] 10,300

South Africa, Republic of	136,000	13,600
United States	151,500	109,000
Other countries	23,600	42,900
Total free world	574,350	581,300

[1] Malagasy Republic.

NONMETALS

Asbestos.—Over 60 percent of the value of Canada's 1963 nonmetals output was accounted for by the $134.9 million worth of asbestos. The industry embraced 12 companies operating 15 mines with a total mill capacity of about 70,000 metric tons per day. This was a record year, with tonnage up 5 percent and value 4 percent higher than in 1962. As usual, most of the production came from established operations in Quebec (1,050,114 tons), Ontario (30,586 tons), and British Columbia (57,152 tons). A new mine and 4,500-ton-per-day mill operated by Advocate Mines, Ltd., a subsidiary of Canadian Johns-Manville Co., Ltd., at Baie Verte, initiated Newfoundland as an asbestos producer in July, and Newfoundland contributed 16,102 tons to the national total in 1963. The bulk of the new production will be exported to the United States and to Europe for manufacture of absestos cement.

Gypsum.—Canada increased gypsum output by over 500,000 tons in 1963 and undoubtedly retained its position as the world's third largest producer. Larger volume of sales to U.S. consumers, the principal export market, accounted for most of the increase. Canadian production is by 8 companies operating 14 mine-and-mill plants with a total daily capacity of nearly 28,000 tons. The five plants in Nova Scotia accounted for 83 percent of the national total in 1963, Ontario supplied 7 percent, Newfoundland 4 percent. British Columbia, Manitoba, and New Brunswick contributed small amounts.

The gypsum industry's principal development in 1963 involved Western Gypsum Products, Ltd., of Winnipeg commencing a new underground mining project near Silver Plains, Manitoba, and the completion in May 1963 by the same company of a $3.5 million products plant at Clarkson, Ontario.

Potash.—Drilling for oil in the early 1940's revealed enormous resources of potash (sylvite) in Devonian strata at depths ranging from 3,000 to 7,000 feet under a vast area of western Canada. The formation underlies the entire width of Saskatchewan and extends into both Manitoba and Alberta. More than a decade has been necessary to overcome the technical difficulties of sinking shafts through water-bearing formations and in designing extraction methods. While the major developments have been by two companies, Potash Co. of America and International Minerals and Chemical Corp. (Canada), Ltd. (IMC), some 17 companies held potash land rights and 5 had definite

Digitized by Google

production plans under way in 1963. The sole producer in 1963 was IMC whose mine and refinery at Esterhazy, in eastern Saskatchewan, commenced operation in August 1962. Potash Company of America is expected to resume mine production at Patience Lake near Saskatoon late in 1964. Also late in 1964 Kalium Chemicals, Ltd., is scheduled to initiate solution mining of a sylvite bed more than 5,000 feet deep, near Belle Plaine, 25 miles west of Regina.

Heretofore Canada's requirement of potash fertilizers and chemicals of about 200,000 metric tons annually, has been imported from the United States and Western Europe. Official Canadian trade statistics have not reported exports of potash. However, recorded U.S. imports of potash materials from Canada in 1962 and 1963 probably represent the bulk of Canadian production. By 1970, an annual output capacity of 5 million tons is envisaged; enough to supply half the 1963 world requirement.

Sulfur.—Recovery of sulfur as a byproduct of natural gas has been the primary factor in increasing Canada's annual output of sulfur over fourfold since 1951 and in thus transforming the national status from that of net importer to that of one of the world's principal suppliers. Production of sulfur in pyrites and pyrrhotite has been decreasing since 1957 when these materials totaled 467,000 metric tons of contained sulfur. Recovery of equivalent sulfur from stack gases in the smelting of base metal sulfide ores, most of which is credited to the Cominco smelter in Trail, British Columbia, and the Inco smelters near Sudbury, Ontario, and Thompson, Manitoba, has increased along with base metals production to record levels of 251,000 to 282,000 metric tons per year in the 1960's.

Recovery of elemental sulfur from natural gas was commenced in Alberta in 1951. Each subsequent year has shown an increase as new recovery plants were added. In 1963, 17 plants (15 in Alberta and 1 each in British Columbia and Saskatchewan) produced 1,053,836 metric tons. This represented an increase of nearly 68 percent over the 630,579 tons production reported in 1962. At yearend, Canadian installed capacity for recovering sulfur from natural gas was stated to be 1,935,650 tons per year.

Sulfur produced from pyrites and smelter gas is consumed largely in manufacture of sulfur chemicals, principally sulfuric acid. Canada's annual output of sulfuric acid has averaged 1,516,000 metric tons in the 3 years 1960–62.

Exports of sulfur in 1963 are the largest on record. The United States, as usual, was the principal market—484,669 metric tons. However, new customers in 1963 included the U.S.S.R. 53,715 tons, the Republic of South Africa 29,010 tons, and Japan 16,823 tons.

MINERAL FUELS

Coal.—Whereas the 1963 Canadian production of 9,594,058 metric tons of coal of all types was slightly higher than in 1961 and 1962, the recent level of production has been the lowest in more than 50 years. The decline has resulted from the almost universal trend toward replacement of coal and other solid fuels by petroleum and natural gas for space heating and energy generation. Moreover, the competitive position of Canadian coals has gradually weakened due to rising costs

Digitized by Google

of production and costs of transportation from mines to consuming centers in Quebec and southern Ontario. For these areas the coal fields of the eastern United States offer economic advantages.

The Canadian coal industry depends heavily on several forms of government aid. The Coal Production Assistance Act makes Federal loan funds available for coal mine development and equipment and for these purposes has in 13 years provided over $12.3 million. Subvention payments on coal transportation totaled $16.8 million in 1963. A total of $1.75 million was paid to compensate operating losses sustained by several mines in Nova Scotia and New Brunswick in 1963. Under the Canadian Coal Equity Act and the Atlantic Provinces Power Development Act, bounty payments are made to consumers of Canadian coal in manufacturing iron and steel and in generating electric power. Payments for these two items in the April 1, 1962 to March 31, 1963, fiscal period totaled $2 million.

A new type of flat-rate subsidy, aimed at assisting the competitive position of coal produced in Nova Scotia and New Brunswick with imported oil, was introduced in 1962. The Nova Scotia producer received 30 cents, and the New Brunswick producer received 10 cents per short ton shipped. The first year's payments totaled $1.2 million.

Coal imports from the United States in 1963 totaled 12,099,000 metric tons (769,000 tons anthracite, 11,112,000 tons bituminous, 213,000 tons coal coke, 5,847 tons briquets). According to estimates by the Dominion Coal Board,[9] consumption of coal in the 1960–63 fiscal periods (April 1 to March 31) is broken down as follows:

	1960–61	1961–62	1962–63
Total consumption, thousand metric tons	20,672	20,698	21,584
Household, percent	21.7	20.9	16.7
Industrial, do	46.3	47.0	52.8
Railway, do	2.5	1.9	1.4
Coke and gas, do	22.3	23.8	23.2
Bunkers, do	1.3	1.1	1.0
Colliery and waste, do	2.0	.9	1.2
Export, do	3.9	4.4	3.7
Total	100.0	100.0	100.0

Coal exports in recent years have been dominated by shipments of Alberta and British Columbia coal to Japan. New contracts with Japanese steel manufacturers call for a total of 2.2 million metric tons of metallurgical type coal over the 3 years beginning in 1964 from Coleman Collieries, Ltd., Vicary Creek mine near Coleman, Alberta, and Crow's Nest Pass Coal Co., Ltd., Michael Mine in eastern British Columbia.

Optimism regarding the future of the Canadian coal industry is found in anticipated use of coal, both imported and domestic, by new thermal electric plants. Increased production is expected with introduction of improved mining and transportation equipment. A continuous mechanical miner was installed recently in the Dominion Steel & Coal Corp., Ltd., Princess mine, and the Bras d'Or Coal Co., Ltd., plans to add an additional Wilcox mechanical miner. Mechanical mining equipment has been adopted by Canmore Mines, Ltd, Canmore, Alberta, and by Crow's Nest Pass Coal Co., Ltd., at Fernie,

[9] Dominion Coal Board (Ottawa). Fourteenth Annual Report, 1961–62.

Digitized by Google

British Columbia. The highlight improvement in coal transportation is the success of self-unloading boats used in the shipping of coal from Cape Breton Island to the Great Lakes and the purchase of such a carrier of 25,000-short-ton capacity for delivery in 1964.

Petroleum, Natural Gas, and Helium.—Production of petroleum and natural gas in 1963 continued the growth trend that has been the rule in Canada for more than 40 years. The year's yields of crude petroleum and natural gas represent alltime production records, respectively 6 and 12 percent greater than the previous year.

Although there were relatively few important new oil discoveries in 1963, the year's increase to known reserves was one of the largest on record. Revisions and extensions in established fields, plus pressure maintenance and secondary recovery projects, raised the total national reserve estimate for petroleum and natural gas liquids from 5.2 billion barrels in 1962 to 5.8 billion in 1963. In addition, renewed interest in the oil sands of Alberta has resulted in a revised estimate of 416 billion barrels recoverable reserves which should eventually yield 300 billion barrels of synthetic crude. Canada's natural gas reserves are currently placed at 39,000 billion cubic feet—about 10 percent above the previous year's figures.

Exploration and development drilling in 2,798 wells during 1963 totaled 11.5 million feet. This was about 10 percent more than in 1962. Most of the drilling—1,800 holes totaling nearly 10 million feet—was development drilling in the known Alberta oil and gas fields. At the seasonal peak, 87 geophysical crews, mostly seismic, were working throughout Canada. This approximately equalled the previous year's level of geophysical activity.

Construction of pipelines for oil, natural gas liquids, and liquid products in 1963 amounted to about 1,000 miles, bringing the total oil line mileage to over 11,000. The longest section built in 1963 was Petroleum Transmission Co.'s 577 miles of 6-inch line to carry natural gas liquids from the new plant at Empress, Alberta, to Winnipeg, Manitoba. Interprovincial Pipeline Co. laid 41 miles of oil pipeline in Manitoba and 126 miles in Minnesota. Gas transmission and distribution lines laid in 1963, respectively 700 and 1,300 miles, brought the total of gas pipelines to more than 43,000 miles.

Capacity of Canada's 43 oil refineries was raised from 988,470 barrels of crude oil per day at the beginning of 1963 to 1,020,000 barrels per day at yearend. Nearly 85 percent of the national capacity is controlled by four companies: Imperial Oil Enterprises, Ltd. (33 percent), Canadian Oil Co., Ltd. (18 percent), Texaco Canada, Ltd. (18 percent), and British American Oil Co., Ltd. (16 percent) Refinery receipts of crude petroleum in September 1963, amounted to 929,666 barrels per day and the year's total output of products, up about 7 percent from the previous year, totaled 331.5 million barrels.

With the addition of 5 new processing plants in 1963, the raw gas annual capacity of Canada's 83 plants went to 1,398 billion cubic feet (equivalent to 3,830 million cubic feet per day). The largest of the new facilities were the British American Oil Co. plant at Lookout Butte and the Imperial Oil Enterprises plant for processing casinghead gas from the Swan Hills region of Alberta.

Digitized by Google

Of particular interest during the year were developments related to the exploration plans for the Athabasca oil sands and the establishment of a helium extraction plant.

The extent and huge potential of the vast deposits of oil sands (also referred to as tar sands and bituminous sands) along the Athabasca River in northeastern Alberta has been known for over a century. However, despite expenditures since 1945 estimated at over $40 million for land acquisition, research, and tests, the problems of economic recovery and marketing have not been solved. Beginning in 1962, industrial interest revived and four companies have recently proposed projects totaling $800 million to produce 245,000 barrels per day by 1970. The Alberta Conservation Board recently approved the application of Great Canadian Oil Sands, Ltd., to undertake a $191 million project to extract 45,000 barrels per day. The board stipulated that the plant must be operating by September 30, 1967. Plans call for an open pit mine operation, and in addition to the oil, the refinery is expected to produce 305 metric tons of sulfur and 2,687 tons of petroleum coke daily. It is expected that following this initial concession one or more of the other project applications by Cities Service Athabasca, Inc., Shell Oil Co. of Canada, Ltd., and Can-Amera Oil Sands Development, Ltd., may eventually be granted.

Following the discovery of commercial occurrences of helium in a deep-test well near Swift Current in 1958 and in the Wood Mountain area in 1960, Canada Helium, Ltd., was formed early in 1963 by British American Oil Co., Ltd., British Oxygen Co., Ltd., and L'Air Liquide of France An extraction plant was built in 1963 near Swift Current in southeastern Saskatchewan. The reservoir which contributes Canada's first helium production (since an experimental operation in 1915–20) contains 1.9 percent helium in a combustible mixture of other gases. The two wells currently in use are estimated to contain 20 years' reserve at the plant's production capacity of 12 million cubic feet of helium per year. Operation commenced late in 1963. In addition to helium, the company also will market liquid nitrogen.

The Mineral Industry of Costa Rica

By Sumner M. Anderson[1]

COSTA RICA constitutes a relatively small market (US$21 million annually) for metals, minerals, and mineral fuels; the country also imports finished manufactures. Completion of a cement plant and a fertilizer plant should make the country self-sufficient or largely so in those products and reduce the total import market by US$4 million to US$5 million.

Mineral production also is nominal, contributing less than 0.5 percent to the gross national product (GNP). Ratios of mineral production value to GNP, in thousand colones,[2] have been as follows:

Year	Value of mineral production (thousand colones)	Share of GNP (percent)	Gross national product (thousand colones)
1961	7,944	0.28	2,852,850
1962	6,767	.22	3,132,150
1963	4,275	.12	3,424,750

Costa Rica has an area of only 19,700 square miles. Its population, estimated in 1963 at 1.3 million, is supported principally by agriculture. Over 95 percent of the people are of Spanish descent; the 88 percent literacy rate is one of the highest in Latin America.

In 1963, Costa Rica was in the early stages of transition from a subsistence coffee-banana export economy to a more diversified, partially industrialized one. The development of mineral resources has been retarded by lack of access into large sectors of the country, inadequate mineral exploration, an obsolete mining code that applies basically to gold mining, and a tradition of speculation on—rather than development of—mine properties. Petroleum exploration has proved disappointing. Bauxite exploration has led to the discovery of large low-grade deposits of commercial potential, and a bill to amend the mining code, reportedly modeled after legislation in force in Jamaica, was submitted for consideration to the legislative assembly on November 7, 1963, for the purpose of facilitating development.

Minerals of construction are abundant, and the recovery of gold has been small in recent years and sporadic since the 16th century; other known resources are limited to minor occurrences or commercially marginal deposits of manganese, iron, copper, lead, zinc,

[1] Chief Latin America specialist, Division of International Activities.
[2] One colón = US$0.15.

Digitized by Google

mercury, nickel, barite, and sulfur. The Caribbean shoreline, particularly in the Puerto Viejo area of Limón Province, contains about 8 million tons of titaniferous iron sands of potential commercial value.

PRODUCTION

Except for salt, the Costa Rican Government makes no attempt to account precisely for the mineral production of the country. The other figures presented in the production table are rounded estimates.

TABLE 1.—Approximate production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:

Lime	3,000	3,800	3,800	3,800	5,000
Limestone	23,000	23,600	24,800	25,000	30,000
Salt, marine	12,504	12,700	11,500	8,950	5,698

TRADE

For many years the total foreign trade balance has been unfavorable. In 1962 the unfavorable trade balance in minerals accounted for US$21 million of the overall deficit of US$26 million. The total trade deficit in 1963 is estimated at US$43 million, but the proportion due to minerals is not available. The trade statistics presented in the accompanying tables are those officially published in Comercio Ex-

[2] Less than 1 ton.
[3] Includes some crude oil and partly refined oil, apparently all for use as boiler fuel.

COMMODITY REVIEW

METALS

Bauxite.—Alcoa de Costa Rica, a local subsidiary of the Aluminum Co. of America, has invested more than US$3 million in exploration for bauxite since 1956 and has found some 150 million tons of material in beds 2 to 2.5 meters (6.5 to 8.2 feet) thick, averaging about 35 percent alumina, in the Valle del General area south of San José. Further development awaits passage of the proposed amendment to the Mining Code and determination of the economic feasibility of treating the low-grade ore in a reduction plant on the west coast of the United States. If these factors prove favorable, a road or railroad must be built from the deposit to a Pacific port.

Gold.—Gold production, estimated by the Banco Central de Costa Rica at 3,000 troy ounces a year, is from individual small-scale placer operations principally on the Osa Peninsula on the southwestern (Pacific) side of the country. Several lode deposits on the west slope of the Cordillera Central were worked in past years but were unable to withstand rising production costs.

Manganese.—In the second quarter of 1963, Metal Surfaces, Inc., a U.S. company working manganese deposits on the Nicoya Peninsula, sent a trial shipment of 600 tons of manganese ore to Japan to deter-

Digitized by Google

mine whether the deposits are sufficiently rich to justify further mining activities. By yearend, results had not been reported.

NONMETALS

Cement.—Costa Rica has the highest per capita consumption of cement in Central America; imports have risen from 37,000 tons in 1951 to 82,000 tons in 1963, and to a cost exceeding US$1.7 million. To curb this drain on foreign exchange and dependence on foreign suppliers, Industria Nacional de Cemento, S.A., is building the country's first cement plant at Cartago, 20 kilometers (12 miles) southeast of San José The plant is scheduled to be completed and operating in May 1964, with an annual capacity of 112,000 metric tons of portland No. 1 quality cement, marketable at a maximum of US$0.93 (6.20 colones) per 94-pound bag. Local materials required for this scale of operation are estimated to be sufficient for 30 years.

Fertilizers.—In August 1963, Fertilizantes de Centro America, S.A., incorporated in Panama and two-thirds owned by the Esso Corp., completed construction of a US$10.5 million chemical fertilizer plant near the west coast port of Puntarenas. Production was to start in September. Anhydrous ammonia supplied by Esso subsidiaries in Cartagena, Colombia, and Aruba, Netherlands Antilles, will be the principal raw material for producing up to 180,000 metric tons per year of complex fertilizers and ammonium nitrate for sale in Costa Rica and throughout Central America. Local sales should reduce substantially the US$2 million per year in foreign exchange previously required for the importation of fertilizers.

Salt.—Production of marine salt is from Pacific Coast salinas in the Provinces of Puntarenas and Guanacaste.

MINERAL FUELS

Petroleum.—Exploratory drilling and seismic operations by the Gulf Oil Company subsidiary, Cía. Petrolera de Costa Rica, were continued in 1963. Refinadora Costarricense de Petróleo has been organized to establish a small petroleum refining industry in Costa Rica using imported crude. Construction of the refinery is scheduled to start in early 1964 at Moin, 8 kilometers (5 miles) west of the Caribbean port of Puerto Limón.

The Mineral Industry of El Salvador

By Henry E. Stipp [1]

EL SALVADOR'S 1963 output of minerals and mineral products, all nonmetals, was valued at approximately US$2 million, 22 percent more than in 1962. This figure represented only about 0.3 percent of the country's gross national product.

El Salvador's population of 2.6 million is supported chiefly by agriculture (with coffee and cotton the principal crops) and by trade. It is estimated that only 0.3 percent of the total working force (806,590 in 1961) was employed by the mineral industry. Some light manufacturing is carried out, utilizing domestic raw material (principally agricultural) or imported commodities. The nation's mineral industry was small in 1963, consisting largely of limestone quarrying for manufacture of lime and cement and the production of salt for local consumption. Most of the metals, nonmetals, and mineral fuels consumed were imported. The government of El Salvador advocates geographic diversification of its exports and imports, to reduce heavy reliance upon any one country as either a source of supply or a market. The government is trying to develop the limited mineral resources that exist. A general inventory of physical resources by the Army Map Service, U.S. Corps of Engineers, in cooperation with the Agency for International Development was advanced during the year. The survey is to provide detailed information on mineral resources, soil, vegetation, rocks, and water by December 1964.

SOURCE MATERIAL

The information contained in this chapter was supplied by the U.S. Embassy, San Salvador, El Salvador, through the U.S. Department of State, and supplemented by "Anuario Estadistico (Statistical Annual)," 1961 and 1962 (volume 1), San Salvador, and "Overseas Business Reports," July 1963, published by the Bureau of International Commerce, U.S. Department of Commerce.

PRODUCTION

Production of limestone for use in the manufacture of lime and cement was the principal mining activity carried out in 1963. A single plant produced the country's total output of cement. Salt was recovered from sea water and brine by solar and other evaporation methods, for local consumption.

[1] Physical scientist, Division of International Activities.

Digitized by Google

Gold and silver were not mined commercially in 1963. Production of gold and silver was last reported in 1960, when output was valued at US$39,000 and US$69,000, respectively.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Gold, troy ounces	2,474	[2] 1,121			
Silver, do	199,080	[2] 76,809			
Nonmetals:					
Cement	83,144	85,214	73,283	63,834	81,690
Lime	([3])	([3])	500	450	[4] 477
Limestone, for cement and lime [4]	107,700	111,700	96,200	83,800	107,100
Salt	12,700	14,000	15,000	18,140	[4] 18,000

[1] In addition to commodities listed, pumice and a slatelike sedimentary rock have been produced, the former for use as an aggregate in cement blocks and for road construction and the latter for construction purposes. Quantity and value of output have not been reported.
[2] One mine produced until May 1960 and has not resumed operations.
[3] Data not available; there was some unrecorded production of limestone for use in the production of lime and in paints.
[4] Estimate.

TRADE

The lack of developed mineral resources has forced El Salvador to rely heavily on imported basic raw materials to supply its small industries. As a result El Salvador has become the leading trader in the Central American Common Market. Total trade established a record high in 1963, with a favorable trade balance.

TABLE 2.—Exports of metals and minerals

Imports for 1963 totaled US$150.8 million, compared with US$130.2 million in 1962. Imports from Central American countries increased 25 percent over those of 1962. The U.S. share of the market remained at 36 percent, despite El Salvador's increased trade with other countries.

Exports in 1963 totaled US$153.6 million, compared with US$138.1 million in 1962. Exports to other Central American countries increased 30 percent over the 1962 figure. The United States, West Germany, Guatemala, and Honduras were El Salvador's principal trading partners in 1963; however, trade with Japan increased.

All imports do	153.0	130.2	
Metals and minerals share in percent total imports.	6.5	9.7	

[1] Approximately 31,000 barrels of petroleum products were reexported to Honduras, Guatemala, and Nicaragua in 1961 and 37,170 in 1962.

COMMODITY REVIEW

METALS

Gold and Silver.—An exploration survey was started in October at the dormant San Sebastián mine, Department of La Unión. Money was being solicited to finance reopening the mine, but funds proved difficult to obtain because of the low metal content of the ore. A Canadian firm was considering reopening the Monte-Cristo mine in the Department of Morazán, which was closed in 1960. This could employ 300 miners.

NONMETALS

Cement.—Plans were made to move El Salvador's only cement plant from Acajutla to Metapán because of depletion of raw materials at Acajutla. The plant has an approximate annual capacity of 1.5 million tons. It is owned and operated by Cementos de El Salvádor, S.A. A loan of US$1,200,000 was obtained from the Central American Economic Integration Bank to finance the move.

Limestone.—Deposits of limestone are located in the Departments of Metapán and Sonsonate. The Metapán deposits were expected to last 160 years at current rates of depletion, whereas the Sonsonate calcareous beds near Acajutla were almost exhausted in 1963.

MINERAL FUELS

Petroleum Refinery Products.—El Salvador's first oil refinery, a US$10 million plant near Acajutla, was officially opened in May. The refinery is operated by Refineria Petrolera Acajutla, S.A., which is

Digitized by Google

owned jointly by Shell (35 percent), Esso (60 percent), and private Salvadoran capital (5 percent). It has a capacity of 14,000 barrels per day of refined products. Crude oil is imported from Venezuela via the Panama Canal. The operating company plans to export products to Guatemala and Honduras. Construction of the refinery has helped the economic development of the country by employing 112 local workers, saving foreign exchange, developing and training skilled labor, and establishing allied industries.

The Mineral Industry of Greenland

By Lester G. Morrell[1]

GREENLAND, the world's largest island (837,000 square miles), formerly a Danish colony, became a fully represented county of the Kingdom of Denmark in 1953. Eighty-five percent of the surface of the island is covered with a mantle of ice 300 to 500 meters thick. The population, estimated in 1963 at 34,000, is mostly Eskimo and is distributed in numerous villages and tiny settlements along the 132,000 square miles of coastal areas that are ice-free for at least part of the year. The country has few known natural resources. The principal occupational activities are fishing and seal hunting. Under a Danish-American agreement for the common defense, several military research projects are maintained by the U.S. Department of Defense.

Mining has been a relatively important element of Greenland's economy for many years. Both coal and cryolite have been produced intermittently since the mid-1800's. Lead and zinc concentrates were produced and exported during 1956–62. Records are vague on several reportedly unsuccessful small-scale attempts to produce copper, graphite, rare-earth minerals, marble, and garnet. Occurrences of other economic minerals have been reported. Iron, molybdenum, and fissionable materials have been prospected in depth, but commercial production of these ores has not been attempted.

The Danish Government is a major participant in all geological investigation projects and mining activities in Greenland. Private companies in partnership with the government are responsible for field activities and technical operations. Legislation relative to concessions and mining is based on the Danish basic law No. 181 of 1950: Law on Exploration and Utilization of Raw Materials in the Subsoil of the Kingdom of Denmark. The most recent Greenland concession under this law in December 1961, when Arctic Mining Co., Ltd., received a 50-year grant of prospecting and extraction rights for molybdenum and certain other minerals in the Mesters Vig area. The Danish Government retains a majority interest in this venture.

SOURCE MATERIAL

Material presented in this chapter is from Danish Government publications, industrial journals, and press, translated and reported by the U.S. Embassy in Copenhagen. Trade data are from the official Department of Statistics publication "Danmarks vareindførsel og-udførsel" (Denmark Products Imported and Exported).

PRODUCTION

Coal was the only mineral reported as being produced in Greenland at yearend 1963. Quantities of indigenous construction materials produced and used within the country are not recorded. The lead-zinc mining and milling operation of the A/S Nordisk Mineselskab (Nordic Mining Co., Inc.), was terminated in 1962, and cryolite production by Øresund Cryolite Co., Inc., was stopped in 1963. Both mines reported depletion of ore reserves.

Nonmetals: Cryolite, crude (exports) [1]	42,041	42,456	41,775	40,943	65,723
Mineral fuels: Coal, bituminous	26,995	28,415	30,139	26,098	40,000

[1] Quantity shown for 1963 is entirely from accumulated stocks.

TRADE

Minerals comprised 15 percent of the value of Greenland's total imports and 31 percent of total exports in 1962. It is anticipated that the importance of minerals will decline in 1963 and succeeding years owing to mine closures; however, shipments from accumulated stocks of crude cryolite will continue for some years. Fuels, foodstuffs, and manufactured products account for most of the imports. Fish and seal products are the principal export items. The bulk of trade is with Denmark.

COMMODITY REVIEW

METALS

Lead-Zinc.—All lead and zinc produced in Greenland has been from the Nordic Mining Co., Inc. mine at Mesters Vig, a small bay off Kong Oscars Fjord on the east coast near the 72d parallel. Shares of the company are held 27.5 percent by Danish Government, 27.5 percent by private Danish investors, and 45 percent by Swedish and Canadian investors. Following exploration and testing during 1950–54, which indicated 500,000 metric tons of sulfide ore averaging 10 to 12 percent lead and 8 percent zinc, a small underground flotation mill was installed and the mine was operated seasonally from 1956 to 1962.

Despite the rigorous climate, the mine was worked (by about 80 employees) 8 to 10 months of each year. The yearly accumulation of concentrates was exported during the brief (approximately August 1 to September 15) season of open water. As anticipated from the beginning, the ore body was mined out and the operation was terminated in 1962. Total recoverable lead and zinc contained in exported concentrates amounted to 48,200 metric tons of lead and 49,850 tons of zinc. These were exported to smelters in Denmark, Belgium-Luxembourg, and The Netherlands.

Molybdenum.—Early in 1962, Nordic Mining Co., Inc., announced that it had joined with American Metals Climax Inc. in a prospecting and exploration venture based on known occurrences of molybdenum near the recently exhausted lead-zinc deposits at Mesters Vig. The newly formed Arktisk Minekompagni (Arctic Mining Co.) will have

Digitized by Google

an initial capital of 6.5 million kroner (1 krone=US$0.145) but this may be increased, if required, to 100 million kroner or more. A majority of the ownership in Arctic Mining Co. must be Danish. The concession is for 50 years and grants molybdenum and certain other minerals (exclusive of cryolite and radioactive materials) in an area of east Greenland between 71°54′ to 72°05′ north and 24°30′ west. The immediate objective is verifying the reported existence of upwards of 50 million tons of granite averaging 0.0026 percent molybdenite (MoS_2).

NONMETALS

Cryolite.—The Ivigtut mine, which until its closure in 1963 was the world's principal source of natural cryolite, is on the southwest coast of Greenland at 61°17′ north, 48°10′ west. The Danish Government owns 50 percent of the Øresund Cryolite Co., Inc., which holds an exclusive concession to mine the cryolite deposits and operates a cryolite-processing plant at Copenhagen, Denmark. During about a century of operation about 3 million metric tons of crude cryolite was extracted. From 1953 to 1963, annual production from the mine, an open pit operation employing 120 to 150 workers, was presumably 80,000 to 100,000 metric tons. Each year approximately half of this was exported and the remainder was accumulated in a stockpile which contained 700,000 to 800,000 metric tons when operation was suspended in 1963. The stockpile may be used to supply regular customers for 14 to 17 years at the present shipping rate.

About three-fourths of the exported crude cryolite goes to the company's processing plant in Copenhagen, and about one-fourth to the Pennsalt Chemicals Corp. at Natrona, Pa. The Danish plant exports refined cryolite to the consumer market of 20 or more mostly European countries; Pennsalt Corp. is the exclusive distributor in the United States and Latin America and also supplies the Aluminum Company of Canada, Ltd., which has exclusive distribution rights in Canada.

MINERAL FUELS

Coal.—Aside from annual reports on production, information regarding coal mining in Greenland has been very meager. Coal production reported in 1959–63 is presumed to represent the combined output of the commercial-scale operation near Qutdligassat on the island side of Disko Island at latitude 70° north, off the west coast of Greenland, and of several smaller mines elsewhere on Disko Island and nearby on the mainland. The Disko Island coal is described as substandard bituminous, high in ash and sulfur. The seams range from 1 to 2.5 meters in thickness. Until about 1960, when a coal cutter was purchased, no mechanical equipment was used in the mines.

A small tonnage of this coal has been shipped in some years to Denmark. However, Greenland traditionally has imported substantial quantities of coal from the United States, Canada, and the United Kingdom.

The Mineral Industry of Guatemala

By Henry E. Stipp [1]

CEMENT has been the most valuable mineral product of Guatemala. Its production increase in 1963 over that of 1962, and equivalent increases in the materials required for its manufacture, offset general declines in the output of metallic ores and concentrates sufficiently to give a 7-percent increase in value to the total mineral-industry production. The minerals industry, which furnished employment for less than 1 percent of the labor force, accounted for 0.8 percent of the gross national product of US$725 million. The labor force was officially estimated at 1.1 million persons in 1950; an occupational census has not been reported since that year. Lack of adequate transportation also has been a major factor retarding exploration and development of mineral deposits.

GOVERNMENT POLICIES AND PROGRAMS

In 1960, Guatemala signed the General Treaty of Central American Economic Integration. Under the economic integration movement, the Central American Bank for Economic Integration was created to help finance industrial enterprises. Several projects have been planned for installation in Guatemala, using loans from the Bank. Loans have been approved for textile, clothing, and printing establishments. Guatemala passed an industrial development law, which was to encourage development of new industries through tax incentives and import duty exemptions. Several government officials have expressed approval of foreign investment with preferred Guatemalan private-capital participation and the provision that such investment be used to establish industries to aid the economic development of the country.

During the year a draft of a new mining code was prepared and submitted to the Minister of Economy for study by the Council of State.

A law was passed that replaced import duties on refined petroleum products with a consumption tax. This equalized taxes on imported and domestically produced refined petroleum products. The law also increased the tax on diesel fuel to 20 percent of the retail price.

The National Economic Planning Council recommended a program of economic and cadastral studies and mapping for evaluating natural resources to be carried out by the Directorate General of Cartography over a 10-year period.

SOURCE MATERIAL

The information contained in this chapter was supplied by the U.S. Embassy, Guatemala City, Guatemala, through the U.S. Department of State and supplemented by Anuario De Comercio Exterior, 1961 and 1962, Guatemala, and Overseas Business Reports, December 1962, published by the Bureau of International Commerce, U.S. Department of Commerce.

PRODUCTION

Production of metals and minerals in 1963 was valued at approximately US$6.0 million (1 Quetzal is equivalent to US$1.00); 7 percent greater than the US$5.6 million value of output in 1962. The value of nonmetals was much larger than that of metals, cement alone accounting for 74 percent of total value of metals and minerals.

TRADE

A sharp reduction in the trade deficit was indicated for 1963 by preliminary estimates of the Bank of Guatemala. Exports rose to approximately US$140 million, almost US$26 million higher than the US$114 million in 1962. Imports also increased to about US$140 million, compared with imports of US$137 million in 1962. Were it not for Guatemalan dependence on foreign sources for minerals and mineral products, which in 1961 comprised 18 percent of the imports but only 1.5 percent of the exports, the trade position would have been balanced in that year. During the first three quarters of 1963 the United States, major trading partner of Guatemala, received 41 per-

Digitized by Google

cent of Guatemalan exports and supplied 48 percent of the total imports. An increase in trade with Central America was apparent during the same period. The bulk of this trade was with El Salvador.

COMMODITY REVIEW

METALS

Antimony.—Several small operations in the Department of Huehuetenango produced antimony concentrates.

Iron.—Small deposits of iron were mined near San Juan, Sacatepequez, and in the Department of Chiquimula. Ore from San Juan has an iron oxide content of 55 percent, and Chiquimula ore contains about 70 percent iron oxide. The iron was used in manufacturing cement.

Lead and Zinc.—The sharp decrease in output of lead and zinc concentrates that occurred after 1961 was attributable to closing of the Caquipec mine of Minera De Guatemala, S.A., in Alto Verapaz. Production of lead and zinc concentrates in 1962 and 1963 probably resulted from cleanup operations conducted by the new mine owners.

Manganese.—Minas y Productos de Guatemala, S.A., mined a manganese deposit of unreported size in the Department of Huehuetenango. Tests of ore indicated a manganese content of 57 percent. Reportedly, operations were primitive and were carried out with a labor force of about 100. The quantity of ore mined has not been reported in official statistics.

Nickel.—Izabal Exploration and Mining Co., a subsidiary of International Nickel Co. of Canada, Ltd., continued exploration of nickel deposits in the Lake Izabal area, near the cities of Quiriqua and El Estor. Investigations have developed 25 to 30 million tons of low grade lateritic ore (1.5 percent nickel). Plans for mining and processing the ore have been deferred pending passage of a new mining code by the Guatemalan Government and granting of a $40 million loan by the International Bank for Reconstruction and Development.

NONMETALS

Cement.—A plan to construct a US$9 million cement plant in the city of El Progreso, Department of El Progreso, was revived. Ce-

mentos Cruz, S.A., a Guatemalan owned enterprise was to receive a US$6 to $9 million loan from a U.S. investment group. The cement operation was scheduled to exploit a high-purity limestone deposit 5 miles from El Progreso. The limestone was reported to be sufficient to support production of 500 tons of cement per day for 300 years. This would be the second cement operation in Guatemala. Cementos Novella, S.A., mined limestone in 1963 for manufacture of cement from quarries in Guatemala City.

Magnesite.—Deposits of approximately 4 million tons of magnesite were discovered in the Lake Izabal region, northeastern Guatemala, by Refractories, Ltd., of Guatemala City. Plans have been initiated to mine and process between 40,000 and 50,000 tons of magnesite per year for sale in the United States, South America, and Japan.

Silica.—There is no known glass production in Guatemala; however, various firms have made studies of the resource potential for supporting a glass industry. The Central American Institute for Investigation and Industrial Technology has conducted feasibility studies on the subject. Deposits of silica are currently being mined for use in cement producing operations.

Stone.—A rock-crushing plant to produce gravel for highway construction was erected near Amatitlán. The plant was expected to produce 500 cubic meters of crushed stone daily.

MINERAL FUELS

Petroleum.—There was no exploratory drilling in 1963. Standard Oil Co. of New Jersey (ESSO), which has been drilling in the Peten region, terminated its activities in October 1962 with completion of a dry hole. Two other organizations that had planned to drill abandoned these plans after the ninth dry well was drilled in Guatemala.

Refinery Products.—The first petroleum-refining plant in Guatemala, jointly owned by Standard Oil Co. of California and the Shell Oil Co. of Canada, Ltd., began operating near Matiás de Gálvez early in 1963. Construction was started on a second refining plant near Escuintla by the Texaco Co. The plant and a pipeline between the plant site and the port of San José was estimated to cost US$10 million. The plant was scheduled to start operating at the close of 1964.

The Mineral Industry of Honduras

By Henry E. Stipp [1]

THE QUANTITY and value of most metals and minerals produced by Honduras in 1963 increased significantly. Silver output decreased slightly in quantity, but increased in value. Approximately 0.3 percent of the labor force of 579,400 persons (1961 census) was employed by the minerals industry. Minerals resources of the Republic include gold, silver, copper, lead, zinc, cadmium, antimony, mercury, salt and coal; however, transportation difficulties have hindered exploration and exploitation of many prospects.

GOVERNMENT POLICIES AND PROGRAMS

The government of Honduras has recognized and guaranteed the freedom of private enterprise. Laws accord the same rights and privileges to foreign private capital as prescribed for domestic capital. In 1960, Honduras signed the General Treaty of Central American Economic Integration (the Central American Common Market), which provided for free circulation of persons, goods, and capital within member countries. A common tariff on commodities coming from nonmember countries also was provided. A unified customs area was planned for 1965. The government has studied the feasibility of building a network of roads in the Sula Valley Department of Cortes to aid transport of goods to market. The Inter-American Bank for Economic Development authorized a loan of $1.5 million for construction of these roads, which should also enhance the potential for discovery and development of economic mineral deposits.

A hydroelectric plant was being constructed by the government at Lake Yojoa. Power, which will be available in 1964, will benefit many industrial establishments such as the El Mochito mine of the New York & Honduras Rosario Mining Co.

SOURCE MATERIAL

The information contained in this chapter was supplied by the U.S. Embassy, Tegucigalpa, Honduras, through the U.S. Department of State. It was supplemented by Commercio Exterior de Honduras, 1961 and 1962; Tegucigalpa, May 1963.

PRODUCTION

The value of Honduras metal and mineral output in 1963 increased 3 percent over that of 1962. Silver was the only commodity to decrease

[1] Physical scientist, Division of International Activities.

Digitized by Google

in quantity. One producer reported a decline in the silver content in its ore, which was countered somewhat by increased efficiency of metallurgical recovery processes.

TRADE

Honduran imports in 1963 totaled US$95.1 million, compared with US$79.8 million in 1962. Imports from other Central American countries increased 50 percent over those of 1962; those from the United States increased 10 percent. Commodity gains were most significant in manufactured, processed, and semiprocessed materials and food. Exports (including reexports) increased to US$83.5 million from US$77.2 million in 1962. Exports to Central America, consisting principally of agricultural products, increased by 3 percent. Most of the foreign trade was with the United States, Guatemala, and El Salvador. Imports from Nicaragua and Costa Rica were up sharply.

TABLE 2.—Exports of metals and minerals

COMMODITY REVIEW

METALS

Two mining companies were active in 1963, producing metal and metal concentrates from sulphide and oxide type ores. Compania Minera Los Angeles, S.A., produced lead and zinc concentrates that also contained silver and cadmium at its mine near the town of Valle de Angeles, Department of Francisco Morazán. The New York & Honduras Rosario Mining Co. produced lead and zinc concentrates and gold and silver bullion at its El Mochito mine near Lake Yojoa, Department of Santa Bárbara. The entire output of these companies was exported to the United States.

Gold.—Four locations were recommended by a nonprofit Honduran organization for exploration of possible commercially workable gold deposits. A cyanide extraction plant was scheduled for construction at one site near Moramulca. Another deposit at El Transito was considered to be too small for mining by a large organization. A thorough sampling of the surface was recommended for a location at Alhambra, Department of El Paraiso. At Clavo Rico, near the town of El Corpus, investigation by two organizations disclosed a small high-grade ore zone of unknown lateral extent.

Iron and Steel.—A semi-integrated steel mill of 50,000 metric tons billet capacity was planned for erection in Honduras. Eight to 10 million tons of high-grade magnetite was estimated to be available probably from beach sands and magnetite deposits in the vicinity of Tegucigalpa. A limited supply of coking-grade coal was indicated. Charcoal could be used instead of coke.

Lead and Zinc.—Compania Minera Los Angeles, S.A., was developing deep underground workings at its Las Animas mine, 35 kilometers east of Tegucigalpa. The main shaft was deepened 500 feet below the

Digitized by Google

main haulage level and new lateral levels were driven to expose ore veins. A 6,000-foot drainage tunnel also was started to dewater the mine.

Silver.—The New York & Honduras Rosario Mining Co. planned to double its milling capacity at its El Mochito mine by 1966. The company ore reserve was estimated to be 1,019,000 tons.

On December 20, a 5-percent tax was levied on exports of silver concentrates.

NONMETALS

Cementos de Honduras obtained a $1.5 million loan from the Central American Bank for Economic Integration to purchase equipment for increasing production from 150 tons to 300 tons of cement per day. The plant, established near San Pedro Sula in 1959, exported more than US$500,000 worth of cement to other Central American countries in 1963. It was the only cement plant in the country.

MINERAL FUELS

Coal.—Bituminous and sub-bituminous coal beds near Danli, Pataste, and Moroceli, Department of El Paraiso; Yoro, Department of Yoro; and Sabanagrande and Curarén, Department of Francisco Morazán are estimated to contain 5 million tons of coal. None are developed.

Crude Oil.—Pure Oil Co. capped a dry hole in the Mosquitia area near Puerto Lempira, Department of Gracias a Dios, where it had invested more than US$2 million in exploration. The company had no plans to resume drilling.

Petroleum.—Honduran requirements for more than 1 million barrels of petroleum products and half a million barrels of crude and semirefined petroleum annually have been supplied by imports from The Netherlands Antilles, Trinidad, and the United States. Crude and partially refined petroleum was probably used as fuel oil. No new concessions were granted in 1963. The new Petroleum Code was adopted and the Petroleum Law was amended to make it conform with the new code.

The Mineral Industry of Mexico

By Henry E. Stipp [1] and Sumner M. Anderson [2]

MEXICO is one of the leading mineral producing countries of the world. In 1963 it was first in output of silver, as it has been for many years, and produced significant quantities of copper, iron, lead, zinc, sulfur, fluorspar, petroleum, and natural gas. Approximately 24 other metal and mineral commodities were produced in various quantities. A large part of the smelting and refining of metals and the refining of petroleum was carried out within the country. The increase in value of metallic and nonmetallic mineral production from US$614 million in 1962 to about US$650 million in 1963 was in part due to increased prices on the world markets for silver, copper, and lead, although production of silver and copper increased in quantity as well. The mining industry employed an estimated 55,000 persons in 1963, about 0.4 percent of the estimated 13.8 million labor force.

Exports of metals, nonmetals, and mineral fuels were estimated at about US$268 million in 1963 compared with US$233 million in 1962. The United States continued to be the primary market for Mexican metals, nonmetals, and mineral fuels, receiving over US$160 million or about 60 percent of Mexican exports.

Mexican imports of metals, nonmetals, and mineral fuels were insignificant compared with exports.

The mineral industry as a whole accounted for 28 percent of the foreign exchange earnings in 1963, although according to the Mexican Confederation of National Chambers of Commerce the national economy was becoming less dependent on mineral exports.

Of the reported 1963 Mexican gross national product (GNP) equivalent to US$6.7 billion in terms of 1950 dollars, the mining industry provided 1.9 percent, or US$134 million; while petroleum and coke producers supplied 3.3 percent, or US$221 million. Data are not reported separately on the contribution of several sectors of the total mineral industry, including the iron and steel, cement and other construction materials, ceramics, and mineral fertilizer industries; these are grouped with other industries in official statistics. The relationship of the minerals industry to other sectors of the economy, in terms of contribution to GNP in constant (1950) dollars, and rate of growth during 1963 was as follows:

[1] Physical scientist, Division of International Activities.
[2] Chief, Latin America specialist, Division of International Activities.

GOVERNMENT POLICIES AND PROGRAMS

The policy of the government of Mexico continued to be to foster and promote the development of the nation's economic and social welfare by and for Mexicans. Since the reform constitution of 1917 the policy has effected a more balanced integration of economic and social progress than in any other Latin American republic, but has not provided an environment conducive to the most expeditious development and utilization of mineral resources. Chief among the deterrents has been the heavy burden of multiple taxation imposed on the mineral industry. The petroleum segment and the major part of the coal segment of the industry have been nationalized; iron ore, sulfur, and a growing number of other mineral resources have been placed in the national reserve.

Mexicanization of the mining industry was introduced by the new Mining Law of February 6, 1961, which restricted the issuance of new mining and treatment plant concessions to Mexicans or to companies, the majority of whose capital has been subscribed by Mexicans. Foreign companies were permitted to continue holding and operating the concessions granted to them previously under the terms of their original agreements for an additional 25 years, but were encouraged to "Mexicanize" by being offered a 50-percent reduction in production and export taxes to do so. By 1963 most foreign companies had exercised this option by selling 51 percent of their stock to Mexican nationals, but found the Mexican Government extremely slow in effecting the tax reduction provision. In July 1963 additional legislation was passed to permit Mexicanization by deposit of 51 percent of company shares in trust in the Bank of Mexico for subsequent sale to qualified Mexican investors. (The American Smelting & Refining Co. had been unable to find sufficient Mexican capital offerings for Asarco's majority stock.) An analytical report of the objectives and results of the 1961 Mining Law was published in 1963.[3]

A presidential decree of August 17, 1963, created an exception to the prohibition against export of iron ore from deposits in Baja

[3] Mining World. Mexicanization: It's Impact on the Mining Industry of Mexico. V. 25, No. 3, March 1963, pp. 12–15.

Digitized by Google

California. The Secretary of Industry and Commerce was given authority to allocate a 10-million-ton quota among persons or companies qualifying as exporters under certain conditions.

Officials reported that the government would develop, directly or indirectly, the Peña Colorada iron ore deposits in the state of Colima.

Compañía Minera Asarco, an affiliate of American Smelting and Refining Co. of the United States, brought suit in Mexican courts to stop enforcement of a presidential decree canceling titles to the company's coal mines near Nueva Rosita, Coahuila, which had been excluded from the original nationalization of coal deposits. The courts ruled that the decree put private mine owners in the same position as the possessors of ordinary mining concessions, antedating the effective date of the 1961 Mining Law. A later presidential decree (August 17, 1963) in effect ratified the finding of the federal court and declared invalid certain sections of the decree (August 30, 1963) that canceled private rights to exploit coal deposits.

The mining law of 1961 was expected to be amended as proposed by the Small Miner's Association and the Mexican Mining Chamber. The amendments probably would remove onerous obligations imposed in the 1961 law and regulations of 1962 on filing and marking of claims and restore some rights to prospectors. The changes reportedly would benefit the entire industry.

The Mexican Government has passed a law whereby a company would be required to share a certain amount of its profits with its labor force.[4] The exact form of the law was being studied by a commission for enforcement purposes. This law could negate recent attempts of the Mexican Government to ease the tax burden on its mining industry.

Extensive mineral rights in the state of Durango were taken into the national mineral reserve program, apparently for exploitation of the iron, chrome, cobalt, copper, nickel, and manganese deposits.[5]

SOURCE MATERIAL

The information contained in this chapter was supplied by the U.S. Embassy, Mexico City, Mexico, through the U.S. Department of State. It was supplemented by Revista de Estadistico May 1962, February 1963, and February 1964, and by Annuario Estadistico del Comercio Exteriór de Los Estados Unidos Mexicanos, 1962. Mexican Government sources are not permitted to release data showing the production of individual mines or companies. Several publications from which supplemental information has been extracted are cited in other sections of the chapter.

PRODUCTION

Mexican mineral statistics, which have never held the finality implied by assembly to the last digital unit, have always been particularly enigmatic in the latest year of availability—in this instance 1963. Measured in value of output as estimated by the Direccion de Minas y Petroleo, Mexico's mineral production in 1963 increased over that of 1962 by 8.6 percent in metals and 7.5 percent in nonmetals. According

[4] Engineering and Mining Journal. Metal and Mineral Markets, Oct. 14, 1963, p. 8.
[5] Mining Annual Review (London). Mexico, June 1964, p. 221.

Digitized by Google

to values ascribed by the Direccion de Estadistica, however, the value increases were 10.7 percent for metals and 8.1 percent for nonmetals. Adding to both of these the 2.8-percent increase in the dominant petroleum sector of the industry as estimated by the Banco de Mexico, the overall gain in total mineral output value was 5.0 percent, using Direccion de Minas y Petroleo figures, or 5.6 percent, using Direccion de Estadistica figures.

These group discrepancies do not appear to be overwhelming, and examination of individual items shows no appreciable contradictions in the reported increases for tin, cement, sulfur, and coal, or decreases for arsenic, molybdenum, tungsten, fluorspar, and salt. For other items, however, differences vary as follows, and are particularly significant for such high-value commodities as gold and silver, iron ore, lead, and manganese ore. As shown in the following table, the up-and-down trends in gold, manganese, and graphite are reversed by the two agencies.

Commodity	1963 production, as reported by Direccion de Minas y Petroleo			1963 production, as reported by Direccion de Estadistica		
	Quantity (metal content) metric tons	Value (thousand pesos)	Percent change from 1962	Quantity (metal content) metric tons	Value (thousand pesos)	Percent change from 1962

TRADE

Exports of metals, nonmetals, and mineral fuels increased 15 percent in value from US$233 million in 1962 to approximately US$268 million in 1963. Exports of gold decreased by 18 percent in quantity and value in 1963. The metal ranked 10th as an exchange earner. Greater use of gold in the creative arts and coinage was reported to be responsible for the decrease in exports. Silver exports increased 37 percent in quantity and 62 percent in value. A large part of the increased volume of silver exported was reported to come from stocks, inasmuch as production increased only 3.6 percent over that of 1962. Exports and value of copper increased 21 percent over 1962. Lead exports were about the same in quantity, but value increased by 13 percent. The major metallic export was zinc; however, despite favorable prices, the quantity and value decreased, 5 percent and 4 percent respectively from that of 1962. Some U.S. importers were unable to obtain supplies. Exports of antimony, graphite, arsenic, bismuth, and cadmium increased in quantity and value 1 percent, 2 percent, 11 percent, 15 percent, and 20 percent respectively. Exports of other metals that decreased in quantity and value included mercury 6 percent, tin 53 percent, tungsten 53 percent, and molybdenum 30 percent. The decrease in tin reflected increased use of the metal by Mexican processors.

Iron ore exports decreased 98 percent both in volume and value in 1963, reflecting increased domestic demands of the growing steel industry, which also apparently accounted for the 13 percent drop in the volume and value of manganese shipments. Sulfur exports increased 10 percent in volume and 13 percent in value over that of 1962. Exports of crude and residual fuel oil increased 2 percent during 1963. Most of this went to the United States by special agreement. Facilities are not available in Mexico for converting certain types of crude containing heavy fractions, such as coke, to petroleum products.

Mexican imports of metals, nonmetals, and mineral fuels in 1963 were negligible. Small quantities of petroleum products were imported from the United States to supply Baja California, owing to poor Mexican facilities for transporting oil to that region. Authorities were considering importing reconstituted crude from Venezuela or Libya to keep certain refineries operating at full capacity. Petroleum products from this crude would be exported to Europe.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Antimony:			
Ore	9,493	12,062	All to United States.
Mixed bars	89	172	United States 166.
Refined bars	41	103	All to United States.
Arsenic oxide	13,343	8,473	Do.
Bismuth:			
Mixed bars	1,344	300	Do.
Refined bars	93	124	United States 114.
Cadmium:			
Concentrate	----------	45	All to United States.
Refined	47	28	United States 17; France 7.
Dust	1,160	1,054	All to United States.
Copper:			
Ore and concentrate	3,553	7,022	United States 7,002.
Mixed bars	21,079	24,435	United States 22,247; Italy 1,494; West Germany 694.
Refined, ingots, anodes and bars.	3,382	5,009	Brazil 3,972; United States 657; Argentina 380.
Semimanufactured alloys	629	1,269	Colombia 302; Puerto Rico 250; United States 236; Uruguay 177.
Gold troy ounces	42,988	36,435	United States 36,430.
Iron and steel:			
Iron ore	122,768	147,056	All to United States.
Pig iron	46,096	264	United States 260.
Ingots	1	6,978	Venezuela 6,966.
Sheets, plates, and strip	5,770	23,391	United States 19,286; Brazil 3,445.
Bars	4,687	34	United States 28.
Girders and beams	(1)	48	All to Guatemala.
Wire	449	89	United States 83.
Pipes, tubes and accessories	15,523	17,993	United States 16,075; El Salvador 828.
Ferroalloys	2,616	5,083	All to United States.
Lead:			
Ore, concentrate, matte and speiss.	3,959	4,413	Do.
Mixed bars	17,664	10,575	United States 4,390; Netherlands 2,629; Sweden 2,234.
Antimonial bars	1,603	341	Venezuela 120; Sweden 102; United States 91.
Refined bars	150,533	123,507	United States 79,663; Belgium 13,582; Italy 7,632; Netherlands 7,607.
Oxides:			
Litharge	16,875	20,704	United States 15,165; Italy 1,439; Venezuela 810; Netherlands 736.
Red lead	1,567	2,012	West Germany 567; Netherlands 485; United States 360.
Manganese:			
Ore	36,860	37,315	All to United States.
Concentrate	140,297	95,058	United States 95,018.
Mercury 76-pound flasks	19,248	21,734	United States 13,561; Japan 4,341; United Kingdom 1,240.
Molybdenum concentrate	21	113	United States 70; Netherlands 22; France 21.
Silver troy ounces	30,774,529	33,544,541	United States 14,455,488; West Germany 10,519,594; United Kingdom 2,595,114.
Tungsten concentrate	452	61	All to United States.
Zinc:			
Ore, concentrate and other impure forms.	412,593	358,768	United States 351,307.
Refined	27,763	29,411	United States 10,219; Brazil 9,256.
Other metals	12	32	Mainly to United States.
Total value, metals thousand pesos	1,611,924	1,520,224	
Nonmetals:			
Abrasives:			
Industrial diamond carats	40,000	60,000	All to United States.
Pumice	235	1,606	Do.
Barite	126,656	219,741	Do.
Cement	3,616	13,104	Do.
Clays:			
Bentonite	11	1	All to Colombia.
Refractory	168	226	United States 200; Colombia 15.
Flourspar:			
Acid grade	75,825	96,089	United States 93,702.
Ceramic and metallurgical grades.	338,623	372,215	United States 286,067; Canada 86,078.
Fertilizer, phosphate rock	24,344	27,727	All to United States.
Graphite	17,637	30,218	United States 30,172.

See footnote at end of table.

TABLE 3.—Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals:			
Aluminum:			
Ore, bauxite	8,949	7,363	All from United States.
Aluminum oxide	1,958	2,863	United States 1,518; West Germany 1,296.
Ingots and equivalent primary forms.	10,333	15,924	United States 14,335; Canada 789; Austria 788.
Semimanufactures and scrap.	296	1,480	United States 1,072; Canada 301; Switzerland 73.
Cobalt kilograms	6,576	7,717	Belgium 7,700.
Copper:			
In primary forms:			
Unalloyed	11	29	West Germany 24.
Alloyed	8	27	United States 14; West Germany 13.
Semimanufactured alloys and scrap.	316	245	United States 148; West Germany 79.
Gold:			
Wire troy ounces	12	12	All from United States.
Sheets do	3,070	3,412	West Germany 2,872; United States 540.
Powder do	13,354	6,646	United States 6,636.
Iron and steel:			
Iron ore	38	6,019	Venezuela 6,000.
Ferroalloys	1,576	1,535	United States 865; West Germany 310; Belgium 158.
Pig iron	436	(1)	All from United States.
Scrap	368,369	288,675	United States 288,609.
Ingots and castings	1,916	864	United States 663; West Germany 104.
Sheets, plates, and strip	12,698	10,652	United States 7,649; Japan 797; West Germany 611; United Kingdom 498.
Bars	11,852	11,722	United States 5,011; West Germany 2,057; United Kingdom 1,508.
Girders and beams	5,465	2,727	United States 1,885; United Kingdom 553.
Wire	4,117	1,376	United States 516; West Germany 492; Belgium 200.
Pipes, tubes and accessories	16,888	9,930	United States 7,344; West Germany 932; Italy 381; United Kingdom 338.
Magnesium metal	328	363	All from United States.
Mercury 76-pound flasks	23	17	Do.
Molybdenum	4	1	Do.
Nickel:			
Ingots and castings	337	276	Canada 223; United States 53.
Semimanufactures	149	180	United States 158.
Platinum and platinum group metals. troy ounces	39	159	United States 150.
Silver:			
Wire troy ounces	2,500	5,566	West Germany 3,360; United States 2,206.
Sheets do	1	2	All from United States.
Beaten do	990	461	West Germany 269; Belgium 128; United States 64.
Tin:			
Ingots long tons	181	195	United States 142; United Kingdom 50.
Semimanufactures do	85	2	All from United States.
Tungsten, in all forms	5	6	Do.
Uranium, thorium, kilograms plutonium, and other substances.	1,891	1,121	United States 721; United Kingdom 171; Netherlands 114; Canada 103.
Other nonferrous ores and concentrates.	10,330	18,085	Canada 12,106; United States 5,385.
Other nonferrous metals and alloys	890	1,233	Mostly from United States.

COMMODITY REVIEW

METALS

Aluminum.—Mexico inaugurated its first aluminum smelting plant at Veracruz on July 11. The smelter, built at a cost of about US$17 million by Aluminio, S.A. de C.V., was reported to have a 20,000-ton-per-year capacity. The Aluminum Co. of America (ALCOA), which owns 35 percent of the stock of Aluminio, S.A., is supplying alumina, aluminum fluoride, cryolite, and other material. Mexican nationals

Digitized by Google

own 51 percent of the stock of Aluminio S.A. American and Foreign Power Co. holds the remaining stock. The Federal Electricity Commission of Mexico supplied electric power for the plant.

Copper.—Compañía Minera de Cananea, S.A. de C.V., a subsidiary of the Anaconda Co., was planning to close down all underground mining operations at Cananea, Sonora. The company expected to continue open-pit mining operations. In order to continue mining on a profitable basis, the company reportedly will have to dismiss 400 miners. The 840 men employed in open-pit mining were not expected to be affected.

Cananea's mine output of copper was sent to Cobre de Mexico, in the Federal District, for refining.

Gold and Silver.—Mexico easily maintained its dominant position among the world's silver producing countries, leading the United States, its closest rival, by approximately 7.7 million troy ounces. The gold-silver mining operations of Minas de San Luis, S.A., at Tayoltita, Durango in the Sierra Madre Occidental were described in midyear;[6] the review covered history, geology, mining methods, crushing facilities, cyanidation mill operations, precipitation and refining methods, and transportation problems.

Iron and Steel.—Iron ore reserves were estimated at 244 million tons.[7] Iron ore deposits in the Las Truchas region of Michoacán were investigated. They were reported to be adequate for establishment of a steel plant.

Extensive deposits of iron ore were discovered on the border between the States of Colima and Michoacán, near the west coast.[8] Iron content of the ore had not been reported; however, it was thought to be the same type as high-grade deposits at Peña Colorada, Colima, and at Las Truchas, Michoacán. The deposit was said to be about 50 million tons.

The government-owned steel producer, Altos Hornos de Mexico estimated that its production would increase 15 percent over that of 1962 Expansion projects currently being carried out will give the company capacity to produce 1.2 million tons of steel ingot by 1964–65 if completed on schedule.

A report entitled "Projections of Demand for Steel in Mexico, 1963–70," was prepared by Surveys and Research Corp. under contract with the Export-Import bank.

Lead and Zinc.—In February, the Mexican Ministry of Industry and Commerce imposed export licensing controls on exports of lead oxides to the United States. Exports of lead pigments to the United States have been increasing for several years causing concern among U.S. producers.

Minera Frisco, S.A., sold 51 percent of its stock to a group of Mexican nationals for a reported US$3,440,000 to comply with the Mexicanization laws. The parent firm, San Francisco Mines of Mexico, Ltd., which holds 49 percent interest in Minera Frisco, announced completion of arrangements for Mexicanization in July 1963.

Digitized by Google

The Mexican firm Minerales de Chihuahua stopped shipments of zinc concentrate to the American Zinc Co. of Illinois, failing to comply with terms of a contract between the two companies. Minerales de Chihuahua took this action to comply with a request from a Mexican Government agency to obtain a higher price for its product. Reportedly, Minerales de Chihuahua was to ship 58,000 tons of zinc concentrate to Japan during 1963–65.

A zinc refinery was being constructed at Saltillo, State of Coahuila by Syndicat Belge d'Entreprises à l'Etranger. The plant was scheduled to begin operating late in 1964, using the Overpelt-Lommel refining process.

Molybdenum.—Tidewater Oil Co. obtained 49 percent ownership in Minera Galaviz, S.A., a Mexican corporation with facilities in Sonora, Mexico. An exploration program was started to determine ways to expand mining and milling activities.

Tin.—A tin deposit was discovered by exploration geologists near the mouths of the Bolanos and Santiago Rivers, in the State of Nayarit, south of the Durango tin fields.

Uranium.—Reserves of uranium ore in the State of Chihuahua were reported to be 1.5 million tons.[9] A French company was designing an extraction and refining plant. A pilot plant was said to be producing uranium oxide and metal in Mexico City.

NONMETALS

Fluorspar.—In February, export licensing controls were instituted by the Mexican Ministry of Industry and Commerce on shipments of fluorspar to the United States. This action was taken in an attempt to stabilize export prices for Mexican fluorspar

A drying unit was installed at Minera Frisco, S.A., fluorspar plant, in the Parral district, Chihuahua. Fluorspar concentrates, 99.9 percent dry containing not less than 97 percent calcium fluoride were prepared with aid of the unit.

Sodium Compound.—A plant with an annual capacity of 36,000 tons of sodium sulphate was being constructed for Mexicana de Peñoles, S.A. It will concentrate solutions by vacuum evaporation.

Sulfur.—Stock of sulfur in Mexico (all types) at the end of 1963 totaled 849,552 metric tons. Pan American Sulfur Co. planned to ship liquid sulfur to Europe beginning in 1965.

Compañía Mexicana Metalurgica Peñoles, an affiliate of American Metal Climax of the United States, revealed plans to construct a plant near Torreon, Coahuila, capable of producing 30,000 metric tons of sulfuric acid annually. The plant will use sulfur dioxide gas obtained from the roasting of zinc ore in the nearby smelter of Mexicana de Peñoles. The acid will be sold to a chemical fertilizer plant. Compañía Zincamex, S.A., projected construction of a sulfuric acid plant near Saltillo, Coahuila. The proposed plant will have an annual capacity of 60,000 metric tons, which will be used for the production of phosphoric acid. Celulosa y Derivados, S.A., signed a contract with Simon Carver, Ltd., for construction of a 100-ton-per-day sulfuric acid plant in the Monterrey area. Construction was to begin in early 1964.

MINERAL FUELS

Coal.—Mexican coal deposits were reported to be the richest in Latin America,[10] a claim certain to be disputed by Colombia. Reserves in the State of Coahuila were estimated at 2,000 million tons. Production of coal derivatives from 1950 to 1963 rose by more than 180 percent, according to a report by Nacional Financiera. Output of coal derivatives in 1962 totaled 29,468 tons, 10.9 percent greater than in 1961. The rapid growth in production of coal products was brought about by the great expansion of Mexico's iron and steel industry.

Crude Oil and Natural Gas.—In 1963 Petroleos Mexicanos (Pemex) drilled 554 wells compared with 639 wells drilled in 1962.[11] Of the 554 wells drilled, 99 were exploratory and 455 were development wells; these activities resulted in completion of 290 oil and 52 gas producers. The 99 exploratory wells totaled 815,881 feet of drilling. They included 53 new-field wildcat wells, which resulted in the discovery of 8 new oil and gas fields. These were the Lagarto oilfield in the Veracruz embayment, the Maguey and Santiago oil and gas fields in the Tampico embayment, the Platanal and Tasajero oil and gas fields in the Isthmus of Tehuantepec region, and the Pamorana, Palmito, and Rodeo gasfields in northeastern Mexico.

The discovery of the offshore Isla de Labos field on the extension of the Golden Lane trend, in the Veracruz embayment was hailed as a major discovery. Development of the new field was underway.

Work was started on 10 more compressor stations. Six were for the Ciudad Pemex-Mexico City gas pipeline and four for the gas pipeline connecting the Reynosa fields with Monterrey, Torreón, and Chihuahua. Three crude oil pipelines that totaled 824 kilometers were planned or under construction as of June 1963. One of these lines was scheduled to transport crude oil from the Isthmus of Tehuantepec and central Tabasco-Campeche areas to Salina Cruz on the Pacific Ocean. From there the crude was slated to be shipped by tanker to the refinery being built at Mazatlán. The other pipelines being built will parallel lines operating at present.

Two natural gas pipelines with a combined length of 542 kilometers were under construction or planned in mid-1963. These were to provide connections between the Mexico City-Guanajuato line and San Luis Potosi, and between Guanajuato and Guadalajara. The capacity of both lines was rated at 1,000 cubic feet per day.

Petroleum Refinery Products.—The combined crude distillation capacity of Mexico's six refineries totaled 469,000 barrels per day as of July 1963. A number of additional refinery facilities were under construction or planned in 1963. The crude distillation capacity of the Madero plant at Tampico was being increased by 15,000 barrels per day, and an alkylation unit was under construction. The 40,000-barrel-per-day crude unit being constructed at Salamanca, Guanajuato, will double the refinery's present capacity. A 12,000-barrel-per-day vacuum distillation unit, a 32,000-barrel-per-day catalytic reformer,

[11] Bulletin of American Association of Petroleum Geologists. Petroleum Developments in Mexico in 1963, v. 48, No. 8, August 1964, pp. 1230–1241.

Digitized by Google

a 17,000-barrel-per-day alkylation unit and a 2,500-barrel-per-day polymerization unit were being erected at the Minatitlán refinery. A 50,000-barrel-per-day refinery was scheduled for construction at Mazatlán, Sinaloa. A coking plant of 18,000-barrel-per-day capacity was planned at the 30,000-barrel-per-day Rosarito refinery, Baja California, which was scheduled for construction in 1963.

Petroleum Products.—There were 17 petrochemical plants in operation at the close of 1963. Petroleos Mexicanos (Pemex) owned eight of these, two were owned by investors associated with Pemex, and seven belonged to private firms.[12] Absorption plant capacity was increased from 250 to 500 million cubic feet per day at both the Reynosa and Ciudad Pemex plants. Total capacity at the La Venta plant was increased to 600 million cubic feet per day. Eleven new petrochemical units were scheduled for construction at Coatzacoalcos, Reynosa, Ciudad Madero, Santa Clara, Chihuahua, and Tlalnepantla. Pemex was granted US$110 million from a US$150 million long-term loan obtained from France, for construction of the plants.

Two private chemical firms received government permission to process basic petrochemicals produced by Petroleos Mexicanos. Adhesivas Pesistal, S.A., was scheduled to produce synthetic tannins from phenol and formaldehyde. The 1,500-metric-ton-per-year plant, which will be located in Mexico City was estimated to cost about US$160,000. Fenoquimia, S.A., was given permission to produce phenol from cyclohexane. The 5,400-metric-ton-per-year plant, to be constructed in Toluca, Mexico was scheduled to cost about US$2 million.

Pipelines were used to transport refinery products and liquefied petroleum gases. A 107-kilometer line paralleling the existing Guanajuato-Morelia connection was the only products line under construction or planned in 1963. The recently completed Pemex City-Mexico City line was scheduled to supply inland areas with refined products. The Minatitlán-Salina Cruz products line was slated to be converted to crude.

The Mineral Industry of Nicaragua

By Henry E. Stipp[1]

NICARAGUA'S mineral industry in 1963 continued to operate at approximately the same economic level as in 1962. Agriculture, the dominant segment of the economy, employs more than half the labor force and contributes 38 percent of the gross national product (GNP). Metals and minerals production in 1963 was equivalent to approximately 4 percent of the GNP. Increases in output of most nonmetallic minerals and in the price of silver balanced decreases in production of the precious metals. In 1962, the total labor force was officially estimated at 510,000 persons. Approximately 0.8 percent of these, or about 4,000 workers, were engaged in the mining industry. Mineral exploration and development was hampered by a restrictive mining law. Before the year ended corrective legislation was being studied by the Nicaraguan Congress.

GOVERNMENT POLICIES AND PROGRAMS

The Government's continued efforts to create conditions favorable to private investment should stimulate mineral exploration and development. Approximately 80 percent of Nicaragua's mining industry was owned and managed by foreign concerns.

The congress ratified four Central American economic integration instruments, including the Uniform Industrial Incentive law. Under this law the Government could grant incentives to new industries and extend benefits to existing industries to help them compete in the Central American Common Market. Mineral industries could benefit from this legislation.

SOURCE MATERIAL

The information contained in this chapter was supplied by the U.S. Embassy, Managua, Nicaragua, through the U.S. Department of State, and supplemented by Memoria De La Recaudación General De Aduanas Por 1961 and 1962, Managua, and Overseas Business Reports, December 1962, published by the Bureau of International Commerce, U.S. Department of Commerce.

PRODUCTION

Nicaragua's production of metals and minerals in 1963 was valued at US$16.5 million, about 1 percent greater than the value of output

[1] Physical scientist, Division of International Activities.

Digitized by Google

in 1962. Output of precious metals (gold and silver), an important part of the nation's economy with a 5-year annual value of over US$7 million, decreased somewhat. Copper production, which has been increasing steadily since 1959, leveled off in 1963. Nonmetals output except for gypsum increased substantially.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

TRADE

Nicaragua's total foreign trade was at a high level in 1962 and continued to flourish during 1963. A favorable balance of trade was indicated in 1963, with exports rising to record levels. Nicaragua received 50.4 percent of its imports from the United States in 1962. Trade within the Central American Common Market increased, but was very small compared with total trade.

Digitized by Google

Gold was the principal metal exported and was important in gaining foreign exchange for Nicaragua. Copper and silver exports were also notable. Imports of aluminum and aluminum alloys, iron and steel, lead and lead alloys, zinc and zinc alloys, fertilizers, crude nonmetallic minerals, sodium carbonate, and sulfur increased sharply; imports of cement and lime decreased.

COMMODITY REVIEW

METALS

Antimony.—Deposits have been reported in the Departments of Estelí and Madriz. The National Development Institute worked with the Atlantic Coast Mineral Development Commission to prepare a work program for exploration of these deposits.

Copper.—Mining of copper on a large scale (by Nicaraguan standards) was started in late 1959 by the Canadian-owned Rosita Mines, Ltd., at Siuna, Department of Zelaya, in ore averaging 4.3 percent copper. A mill was erected to produce for export a concentrate containing 72 percent copper, 0.12 ounce per short ton gold, and 22 ounces per short ton silver. The leach-precipitation-flotation process is used to prepare the concentrate. Sulfide minerals are concentrated by flotation and roasted to provide sulfur dioxide gas for producing sulfuric acid. The acid is used to leach the copper oxide minerals forming copper sulfate. Scrap iron is added to the copper sulfate solutions, precipitating cement copper, which is recovered by flotation in the form of a copper concentrate.

Gold and Silver.—These metals are found in several districts of Nicaragua; however, only three companies operated in 1963, averaging 0.23 ounce of gold per short ton of ore. The three firms follow:

Company:	*Mine and location*
Empressa Minera del Setentrion (formerly Empresa Minera de Nicaragua).	El Limon, near Leon.
Neptune Gold Mining Co	Bonanza, Bonanza. La Reina, Matagalpa.
La Luz Mines, Ltd	La Luz, Siuna.

Lead and Zinc.—These metals are present in ores mined for gold and silver but are not recovered at present and are discarded with the waste material.

Molybdenum, Tungsten, and Vanadium.—Occurrences of these metals have been reported at La Soledad, La Cabuya, and El Portillo in the Department of Nuevo Segovia. The deposits have not been exploited; however, the Atlantic Coast Mineral Development Commission was preparing a work program for their exploration.

NONMETALS

Silica.—The Geological Service of Nicaragua discovered two deposits of siliceous sand suitable for the production of glass. The most important deposit, near Puerto Cabezas, contained 98 percent silica, 1 percent aluminum, and practically no iron. The deposit has more than 1 million tons of sand with good granulation characteristics.

Digitized by Google

The other deposit, near Mosonte, Department of Nuevo Segovia, has 10 million tons of sand containing 86 percent silica, 10 percent aluminum, and 4 percent iron.

MINERAL FUELS

Petroleum Refinery Products.—A refinery built near Managua by an affiliate of Standard Oil Co. of New Jersey was officially opened in mid-April. The plant will use imported crude oil brought in by pipeline from Puerto Somoza. The initial capacity of the new plant, 5,000 barrels per day of fuel oils, diesel oil, automotive gasoline, and kerosine, reportedly is sufficient to supply local demands for these products until 1970. However, requirements for lubricants and aviation gasoline must still be met by imports. A consumer tax placed on the petroleum products sold in the country was designed to replace revenue lost in customs duties formerly collected on imports of these commodities. Demand for refinery products was expected to increase moderately.

The Mineral Industry of Panama

By Sumner M. Anderson [1]

PANAMA'S production of minerals in 1963 was limited to limestone and siltstone for cement in new record tonnages, salt at slightly less than the 1962 level of output, and unrecorded quantities of clay, sand, gravel, and crushed rock used in local brick and tile kilns and for ordinary construction needs. Processing plants using imported metal and crude petroleum included a steel rolling mill in its second year of operation, a few small nail factories, a petroleum refinery in its first full year of operation, and an aluminum extrusion plant which opened in October 1963. The recent awakening of Panama to the potential of a mineral industry in the development of its economy was further emphasized by the adoption on August 22 of Decree Law No. 23, to become operative when published in the Official Gazette, embodying a new and comprehensive Code of Mineral Resources. The code will be applicable to the exploration, extraction, transportation, and processing of "any chemical element or compound occurring naturally as a product of geological and biological process including hydrocarbons occurring in liquid, solid or gaseous state and the artificial deposits, tailings and dumps derived from the foregoing." The objectives of the code as set forth in Article 1 are "to stimulate and regulate the exploration and extraction of minerals, principally through private initiative and investment, in all the territories of the Republic of Panama, and, at the same time, to promote the vigorous development of research, transportation, and processing necessary or convenient to assure the availability of these minerals in a national and international level." The code was based, to a large extent, on studies financed by the International Cooperation Administration and completed in 1958. Copies of the 70-page Official Edition, in either Spanish or English, are available on inquiry to the Director, Department of Mines, Ministry of Agriculture, Commerce and Industries, Panama City, Panama.

The Republic of Panama has had no importance internationally in the primary minerals industries, but has been a small-scale producer in years past of gold and manganese ore. Known minerals, aside from the nonmetals exploited in 1963, include gold, copper, manganese, iron, asbestos, low-grade bauxite, and coal. Exploration for petroleum has been unsuccessful thus far.

PRODUCTION

The only official statistics on mineral production compiled by the Government are those for salt. Production data on petroleum refinery products were supplied by industry sources. Actual and estimated production of metal and cement manufactures, limestone, and siltstone and most of the information in the commodity review was collected from industry sources by D. F. McConville, Third Secretary and Vice Consul, U.S. Embassy, Panama City.

The value of mineral production prior to 1962 has not been reported, but may be safely judged as having represented a negligible portion of the gross national product (GNP). With the initiation of the new petroleum refinery in April 1962, the value of petroleum products alone, as estimated on the basis of exports, contributed approximately 4 and 5 percent, respectively, to the GNP in 1962 (US$491 million) and 1963 (US$525 million).

[1] Fabricated or processed from imported raw materials.
[2] Started October 1963.
[3] Estimate.
[4] Fiscal year ending October 31.
[5] In addition, Panama produces annually over 35,000 tons of clay, about 170,000 cubic yards of sand, and unknown quantities of gravel and crushed rock.
[6] Data not available.

TRADE

The latest official figures published for exports and imports were for 1961 in the Comercio Exterior, Contraloría General de la República de Panamá, which does not list countries of origin or destination by commodities. Industry sources have provided data on 1962 petroleum imports which, when compared to 1961 data, reflect the impact of Panamanian refinery production which commenced in 1962.

Gasoline additives—kilograms	3,401	3,401

[1] US$1.00 equals 1.00 Panamanian balboa.

Exports of minerals and mineral products from Panama are only occasional and very limited, with the recent exception of petroleum products. The U.S. Embassy has been requested to release export statistics for total petroleum products only, because there is only one petroleum refinery in the country. These exports in 1962 and 1963 and the imports of crude petroleum for refinery treatment have been tabulated by destination and origin in table 5.

TABLE 5.—Imports of crude oil and major exports of petroleum refinery products

Origin or destination	1962		1963	
	Quantity (thousand 42-gallon barrels)	Value, f.o.b., U.S. dollars	Quantity (thousand 42-gallon barrels)	Value, f.o.b., U.S. dollars
Imports of crude oil:				
Algeria	532	1,223,241		
Argentina	761	1,484,421	721	1,304,293
Libya	1,157	2,377,402		
Saudi Arabia			338	750,946
Venezuela	5,286	12,034,740	13,645	30,974,790
Total	7,736	17,119,804	14,704	33,030,029
Exports of refinery products:				
Argentina	907	3,145,472	549	1,331,079
Canada	588	2,198,653	997	3,477,473
Dominican Republic	111	222,195		
Jamaica	110	219,362		
Netherlands	134	483,113	1,989	4,021,067
Switzerland			182	364,137
United Kingdom	52	212,732	146	571,441
United States	1,927	5,112,508	3,375	7,317,990
Canal Zone[1]	1,946	6,488,222	4,019	9,079,159
International bunkers[2]	348	1,132,383	914	1,848,928
Total[2]	6,123	19,214,640	12,171	28,011,274

[1] An undetermined quantity of these products was sent to the Canal Zone for storage only and has been, or will be, returned for sale in the domestic market.
[2] Jet fuel sold for consumption at the international bunker at Tocumen Airport is not included.

Unfortunately the usefulness of the petroleum products export figures for both quantity and value is severely restricted by the qualifications listed in the footnotes to table 5. The Panamanian Govern-

Digitized by Google

ment compiles its trade statistics on the basis of figures submitted by the refinery. The company knows the quantities shipped to the Canal Zone for temporary storage, but has no way of knowing what portion of those quantities sold from storage goes to bunker sales and what portion is brought back into Panama by dealers for domestic sale. Consequently the latter is not recorded as imports, and precise totals for exports, imports, and domestic consumption of petroleum refinery products remain unknown.

COMMODITY REVIEW

METALS

Aluminum.—An aluminum extrusion plant of Panamanian ownership opened in October 1963. During the last few months of the year, imported aluminum billets were used to produce various types of tubing, conduit pipes, frames, jalousies, and bars, operating at about 10 percent of the plant's installed annual capacity of 2,700 metric tons. In addition to completely meeting domestic demand for aluminum extrusions, the firm hopes to export a considerable portion of its production to the other Central American countries.

Iron and Steel.—A few small nail factories of unrecorded output have operated in Panama for some time. A new Panamanian-owned steel rolling mill was inaugurated in 1962, using ingots imported from Venezuela. The mill employs about 30 people. In its production year ending October 31, 1963, the firm reported a total production of about 6,350 metric tons from which one 360-ton shipment was exported to Costa Rica. The remainder, marketed domestically, included reinforcing rods sufficient for complete local requirements plus a limited quantity of small steel shapes. Output in the 1963–64 production year was expected to reach almost 11,000 tons. Long-range plans included the possible installation of electric furnaces for melting scrap metal.

NONMETALS

Cement.—The limestone and siltstone listed in the production table, approximately two-thirds of which was limestone, was extracted from the quarries of Cemento Panamá, S.A., as raw material for that company's (and Panama's) only cement plant, which has been in continuous operation since February 1948. Gypsum, the other essential raw material, is imported. The plant employs the wet process, using rotary kilns, and has an annual capacity of 243,758 metric tons (1,314,000 barrels). The portland cement production has been primarily of type I (general-purpose) cement, with limited quantities of type II (moderate-heat) and type III (high-early-strength) for special projects. The company reported 1963 prices at the plant, per 94-pound bag, as follows: type I, $1.30; type II, $1.40 to $1.60, depending on quality; type III, $2.00. Production, while increasing steadily, has been considerably behind plant capacity but in 1961 was only some 1,570 tons short of domestic requirements. In the absence of import data since that year, the approach to complete self-sufficiency in portland cement is indeterminate. Panama's requirements for white cement are met entirely by imports.

Digitized by Google

Cemento Panamá also operates an adjoining asbestos-cement plant, inaugurated in December 1960, which has produced annually about 20,000 units of roofing materials including corrugated and flat sheets and ridge rolls. In 1963 approximately 114 metric tons of asbestos was imported for this purpose from Canada. In the first quarter of 1963, Cemento Panamá opened a new $500,000 plant to produce "Fibrolit", a new construction and insulation material comprised of cement pressed with wood shavings from the native guaramo tree.

Clays.—Panama's only major manufacturer of clay products extracts annually from local deposits 98 percent of its own requirements for clay and shale and imports the remaining 2 percent. Native clay consumed by the firm in 1963 was estimated at 33,100 metric tons. Imports normally have been pyrophyllite from Canada, talc and kaolin from the United States, and glazes from both the United States and Mexico. Manufactures include a variety of structural clay products, sanitary ware, glazed wall tile, and ceramic floor tile. An undetermined quantity of clay is also produced by some 15 to 20 very small brick and tile plants scattered throughout Panama. The country's total requirements for refractory products are met by imports.

Salt.—The production, refining, storage, distribution, and sale of salt are controlled by the Panamanian Government through its Institute of Economic Development. Salt production, by solar evaporation of sea water, was officially reported as 222,274 quintals of 100 pounds each in 1963, representing a 4-percent decline from that of 1962. For the needs of the country, production is supplemented by annual imports of iodized salt and rock salt.

MINERAL FUELS

Petroleum.—Until 1962 all of Panama's requirements for petroleum refinery products, which were approaching 3 million barrels annually, were supplied by imports. On April 24 of that year, a new petroleum refinery known as Refinería Panamá, coowned by National Bulk Carriers, Inc., and the Continental Oil Co., was inaugurated at Las Minas Bay near Colon. Built at a cost of $30 million, with $2.5 million in new facilities added in 1963, the refinery represents the largest private industrial investment in Panama. Preliminary reports of values of crude imports versus refined exports indicate a trade gain to the refinery of $2,094,836 for the remainder of 1962, and a trade loss of $5,018,752 in 1963, without consideration of stocks and domestic sales. An unknown portion of the quantities deposited for storage in the Canal Zone was destined for eventual return to the Republic of Panama for domestic sales, making true exports and domestic consumption indeterminate. Nevertheless, refinery officials have estimated domestic consumption of petroleum products in 1963 as follows:

Digitized by Google

	Thousand barrels
Aviation gasoline	138
Motor gasoline	905
Jet fuel	357
Kerosine	310
Distillate fuel oil	452
Residual fuel oil	1,071
Lubricants, including greases	(1)
Asphalt	52
Liquified petroleum gases	30
Total (excluding lubricants and greases)	3,315

[1] Data not available.

The estimate for jet fuel includes international bunker sales at Tocumen Airport, Republic of Panama.

The Mineral Industry of Cuba

By Sumner M. Anderson [1]

THE ENORMOUS contrast between the mineral economy of Cuba in 1963 and in 1958 was the result of the overall political change to which the total economy of the country was intimately linked. Creation of the Cuban Mining Institute (Instituto Cubano de la Minería) to direct all mining activities in the country was an early act of the new Government after the revolution on January 1, 1959. During the next 2 years, the Government confiscated foreign holdings,[2] including United States investments exceeding $1 billion in value. Foreign mining and metallurgical technicians—predominately from Communist areas—were brought in to reorganize the mineral industries. On January 3, 1961, diplomatic relations between Cuba and the United States were severed, and then on May 2, Cuba announced its full-fledged membership in the so-called Communist Bloc. Fifty-four international treaties assured Cuba of Communist economic support, technical and financial assistance, machinery, raw materials, and manufactures. The Soviet Union agreed to buy some Cuban mineral products, and Czechoslovakia stated that it would buy all mineral production offered for the next 20 years, but in both cases at prices said to be much lower than the world market.

The mineral productivity segment of the mineral economy during and since the period of political metamorphosis, has withstood the political disruption better than has the economy as a whole, but with no direct measure of the magnitude of its cost. The overall economic record is marked with steady deterioration; the annual average per capita income has dropped from $374 in 1957 to $185 in 1963, when Cuba's deficit with the Soviet Union alone reached an admitted $1 billion.

As a mineral producer, Cuba has been of some importance internationally in nickel and chromite and of relatively minor importance in cobalt, manganese ore, and copper. The Cuban output of these items as percentages of total world production and rank among the producing countries of the world, comparing the last year of independence with the first and most recently available years of Communist rule, was as follows:

---

[1] Chief, Latin America specialist, Division of International Activities.

[2] The legal validity of these seizures was upheld by the United States Supreme Court in its decision of March 23, 1964, in the case of Farr, Whitlock and Co. (New York commodity brokers) versus the Banco Nacional de Cuba.

Digitized by Google

	Cuba's percentage of world total			Cuba's rank among countries reporting production		
	1958	1959	1963 (est)	1958	1959	1963 (est)
Nickel	8.0	6.3	4.6	3d of 17	4th of 16	6th of 16
Chromite	2.0	1.6	1.2	8th of 20	13th of 22	12th of 21
Cobalt		.6	1.2		5th of 7	6th of 7
Manganese ore	.6	.4	.5	15th of 43	17th of 44	16th of 45
Copper	.4	.3	.1	21st of 46	26th of 47	27th of 48

Cobalt in commercially recoverable form was first produced in 1959–60, prior to confiscation of the Freeport Sulphur Co.'s operation at Moa Bay. Through 1958 and the early months of 1959, most of the production, plus minor quantities of iron ore, lead (last produced in 1958), zinc (produced only during 1954–57), and silver, contributed to the supply requirements of the United States. Since that time (except for lead and zinc) they have been items of barter for food, machinery, petroleum, fertilizers, and manufactures from the Communist countries.

Cuba's resource position in a few of the metallic ores is stronger than indicated by past production. Most abundant are the world's largest reserves of laterites, estimated at over 3 billion tons [3] (regarded as too high by later authorities) averaging about 46 percent iron, 1.75 percent chromic oxide, and 1 percent nickel. (This ore has been nodulized to 54 percent iron, 1.2 percent nickel, 2 percent chromic oxide, 13.8 percent alumina, and 3.4 percent silica.) The metallic reserve position is approximately as follows:

Ore type	Classification of reserve	Quantity (thousand tons)
Exploitable at 1963 prices:		
Laterites, over 1 percent nickel	Indicated	356,000
Nickel content [1]	do	4,646
Cobalt content [1]	do	370
Chromite, refractory grade	Inferred	2,500 to 3,000
Copper	Unmeasured	Largely depleted
Iron ore, hard	Measured	5,000
Lead	Unmeasured	Small
Manganese ore	Measured	1,219
Do	Indicated	2,946 to 3,810
Tungsten ore, 1.36 percent WO_3	Inferred	55
Zinc	Unmeasured	Small
Not exploitable at 1963 prices:		
Laterites, over 1 percent nickel	(2)	(2)
Iron ore, 50 percent Fe basis	Indicated	300,000
Chromite, 48 percent Cr_2O_3 basis	do	24,000
Laterites, under 1 percent nickel	Inferred	1,653,000
Iron ore, 50 percent Fe basis	do	1,393,000
Chromite, 48 percent Cr_2O_3 basis	do	111,438
Nickel, 0.80 percent	do	13,224
Cobalt, 0.07 percent	do	1,157

[1] Calculated on the basis of an average ore grade of 1.3 percent nickel and 0.1 percent cobalt.
[2] Data not available.

In the nonmetallic group of minerals, Cuba has large reserves of barite, a very small portion of which is of high grade. Common clay, for the manufacture of brick and tile, is abundant, but high-tempera-

[3] Rand, C. F. Iron Ore Reserves of Cuba. Eng. and Min. J., v. 96, No. 18, Nov. 1, 1918.

Digitized by Google

ture clays are lacking. Limestone, widespread throughout the island, is the principal and inexhaustible construction rock and basic raw material for the cement industry, which has never produced as much as 62 percent of its capacity of 1,023,300 metric tons. Marble of excellent quality but unmeasured reserve is quarried at one locality on the Isle of Pines and two in Oriente Province. Gypsum deposits, large and extensive, feed the cement and plaster industries, but in color and content of insoluble matter, are below U.S. import standards. Exposures of magnesite are numerous and small with very little high-grade mineral; most of those tested contain calcium oxide in excess of 10 percent. However, in 1959 the Cuban Magnesite Corp. reported a bed of 50 million tons found by core drilling, with no subsequent information released. Deposits of rock salt in Oriente Province have never been exploited, and Cuba's total salt production has been derived from the sea. Large but unmeasured reserves of pyrite, some of which carry associated values in copper, lead, zinc, gold, and silver, are mined for export as iron-sulfur ores but have never been utilized within Cuba. Plans for their development as a basis for a domestic sulfuric acid industry have been studied. Silica sand, 20- to 200-mesh size, is found along the south coast of Pinar del Rio Province from Cortes to La Coloma and probably beyond. In certain places, the upper 3-foot layer is white and of high purity—over 99 percent silica. The sand is utilized largely for construction purposes and to a minor extent for the manufacture of glass.

The most abundant hydrocarbon material on the island is asphaltite, reserves of which have been estimated at 4,535,000 metric tons, plus 220,000 tons of 5 to 38 percent asphaltic rock. Alteration of the original asphalts has resulted in products varying from glance pitch to grahamite. These asphaltites were mined for use as fuel during the petroleum and coal shortages of World War II, but there has been no production since 1946. Domestically produced crude petroleum and natural naphtha, which has never exceeded the 549,398-barrel peak output of 1956, supplies less than 2 percent of Cuba's requirements for petroleum products. Reserves have not been discovered in signicant volume; they are small but not quantatively definable.

In 1958 the value of Cuban mineral production was estimated at $51.566 million, equal to 2.4 percent of the gross national income. Mineral exports in that year were valued at $49 million, the latest annual total available. Of the production value, 55.8 percent was metallic ores and concentrates (37.7 percent nickel), 37.5 percent nonmetallic minerals and their products (24.6 percent cement), and 1.7 percent crude petroleum and refinery products. Production since that time is estimated to have declined abruptly in 1959 and 1960. Some recovery for nickel and manganese ore began in 1961 and for most other minerals in 1962, with the possible exception of cement and petroleum. In 1963 nickel may have reached over 90 percent of the 1958 level, manganese ore 140 percent, and chromite 75 percent, but qualities and terms of negotiated evaluation are not known, and the national economy as a whole was—and is—supported by Communist subsidy. Most of the recovery has been under the supervision of Soviet technicians and Cuban technicians intensively trained in the U.S.S.R. and

Digitized by Google

Czechoslovakia. Exploration for petroleum has been resumed, with no evidence of success.

Cuban production of metallic ores and concentrates (including nickel oxides and sulfides) provided an income from export sales valued at $28,107,000 (including pyrite) in 1958 but supports no smelting or refining industry. The nonmetallic and fuel minerals, on the other hand, are almost entirely consumed locally (pyrite excepted) by the construction, agricultural, and chemical industries; petroleum production reduces slightly the import requirement for crude to feed the oil refineries. Cuba is entirely dependent on foreign sources for refined metal, and for all metal products except those fabricated in its own rolling mills, small foundries, and machine shops. It has exported all its barite production while importing its own requirements for barite and barium compounds. It is dependent on foreign suppliers for high-quality tile and high-temperature brick, and partially dependent for cement, glass sand, gypsum, and magnesite, which are produced in quantities insufficient to meet local demands. Cuba is self-sufficient in the production of salt and is a net exporter of marble.

SOURCE MATERIAL

Since the end of 1958 information on all branches of Cuba's economic development—including the mineral industries—has been spotty, often incomplete or biased, and largely unverifiable. However, various articles and news notes appearing in technical journals and both domestic and foreign news media have supplied data which could be evaluated against information in the files of the Bureau of Mines to provide what is believed to be a reasonably accurate estimate of production and trade in the major mineral commodities during the past 5 years.

PRODUCTION

The figures presented for the last 4 years of the following production table are necessarily speculative. The San Fernando copper mine in Las Villas Province, the only known source of lead, zinc, gold, and

Digitized by Google

silver, produced no lead since 1958 and is believed to have closed down at the end of 1960. Barite production ceased in early 1959.

The exodus of technical and management talents, the rapid exhaustion of maintenance supplies and replacement parts, and the confusion of organization immediately following the indiscriminate confiscation of private industrial enterprises resulted in a sharp decline in mineral production, which had reached its nadir for manganese ore, nickel, and pyrite in 1960, and for most other minerals in 1961. The immediate remedial action of the U.S.S.R. in supplying engineers and technicians, managers, new and accessory machinery, equipment, and supplies—chiefly from the U.S.S.R., Czechoslovakia, and Poland—arrested the decline and started a recovery, which in 1963 is estimated to have approached the 1959 level of production for nickel and probably to have surpassed it for chromite, manganese ore, cobalt, and pyrite. There is no evidence of a comparable recovery in the production of copper or iron ore, the remaining nonmetallics, or crude petroleum.

TABLE 1.—Estimated production of metals and minerals (except where otherwise noted)

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Chromite, refractory grade	[1] 39,673	[1] 29,732	25,000	35,000	50,600
Cobalt in nickel sulfides, recoverable	90	62		164	170
Copper in concentrate	9,019	[2] 11,842	5,000	5,500	6,000
Gold, troy ounces	[1] 615	[1] 348			
Iron ore	3,000	2,500	2,000	1,000	650
Manganese ore:					
Chemical grade, 81 percent MnO_2	7,048	1,000	1,300	3,000	3,300
Metallurgical grade, 35 to 45 percent Mn	46,300	15,006	68,200	69,000	72,400
Total	[2] 53,348	[1] 16,006	69,500	72,000	75,700
Nickel:					
In oxide with cobalt, recoverable	17,833	[3] 11,382	14,805	14,716	14,700
In sulfide, recoverable	180	1,460		1,887	2,000
Total recoverable	18,013	[3] 12,842	14,805	16,603	16,700
Silver, troy ounces	[1] 215,000	[1] 121,415

TRADE

Before 1960 the United States supplied most of Cuba's import requirements for metals and minerals and their derivatives and manufactures, and in return received the bulk of Cuba's exported mineral raw materials except pyrite, which was sold in Europe. Venezuela supplied Cuban refineries with crude petroleum. Beginning in late 1960, foreign trade in practically all mineral commodities shifted to the Communist countries, which Cuba joined early in the following year. Statistics on this trade are very meager, but the accompanying incomplete tables provide examples indicative of the pattern.

TABLE 2.—Exports of nickel oxides and sulfides, gross weight, in 1962

Destination	Metric tons	Destination	Metric tons
U.S.S.R.	10,000	Hungary	130
Czechoslovakia	7,000		
China	5,000	Total	22,730
Rumania	600

COMMODITY REVIEW

METALS

Chromite.—In its peak year, 1943, Cuba was the world's largest producer of chromite with 321,280 metric tons. In 1963, it probably ranked about 12th, but was still first in the Western Hemisphere. It

Digitized by Google

is estimated that total production of chromite in Cuba from 1916 to the end of 1963 has been about 3 million metric tons of refractory-grade ore and 200,000 metric tons of metallurgical-grade ore. These tonnages were the product of some 18 mines in Oriente, 13 in Camagüey, and 9 or more in Matanzas, plus numerous small scattered prospects in those provinces. The great bulk of the refractory-grade production was from the Camagüey district, north of the city of Camagüey, which appears to have been virtually worked out; the remainder was largely the production between 1918 and 1926 of the Caledonia metallurgical chromite mine in the Mayarí district of north central Oriente. By 1959 production of metallurgical-grade had ceased, and output of refractory-grade ore, averaging about 36 percent chromic oxide was from two mines. The Cayoguan mine of Cía Minera Moa (Felipe Godoy, Francisco Vidal and Associates), in the Moa-Baracoa district of Oriente is the largest chromite mine in Cuba and the only important producer since World War II; nevertheless, it accounted for only 36 percent of the 1960 output. The Lolita mine of Cía. Minera Basica, S.A. (subsidiary of Basic Refractories, Inc., of Cleveland, Ohio), the largest mine in Camagüey, supplied the remainder (19,000 tons) on a 30,000-ton contract to the Commodity Credit Corporation, but presumably completed the contract and closed down the following year. In 1963, with all mines nationalized, Cayo del Medico was reportedly the only producing mine. This is believed to be a new name given to Cayoguan, where total efforts to reverse the downward production trend have been applied apparently with considerable success. However, increasing the supplies of chromite and manganese ore for sale or barter to the U.S.S.R. and other Communist countries in Europe is unavoidably suggestive of carrying coals to Newcastle: The U.S.S.R. is the world's largest producer of both.

Copper.—The Matahambre mine in the Province of Pinar del Rio was discovered in 1912. Since the closing of El Cobre in 1918, Matahambre has been the major copper producer in the country. It supplied 81 percent of Cuba's copper output in 1958 and 86 percent in 1963, but its production tonnage for those years dropped from 10,344 to approximately 5,300. At the end of 1958, the Cuban owners of Minas de Matahambre, S.A., became optimistic over indications that an ore body discovered in a new section might prove big enough to offset the diminishing reserve and prolong the life expectancy of the mine, but production continued to drop after intervention the following year and a 22 percent increase in the labor force.

The remaining 700 tons in 1963 was the product of four mines: Tete Contino, unidentifiable but possibly a new name for the San Fernando mine of Las Villas Province; Mina Grande, also unidentifiable but a possible new name for the Francisco mine in Pinar del Rio; Dora, in Pinar del Rio, operated until 1958 by the Cía. Minera Mantua, S.A.; and El Cobre, in Oriente. In the late 1950's an attempt was made to rehabilitate El Cobre, 10 kilometers west of Santiago de Cuba, which had been the world's third largest copper mine in the early half of the 19th Century. A concentration plant was installed consisting of a large assortment of crushers, a ball and rod mill, seven flotation cells, four tables, and a large tank for precipitation of cement copper. The plant had not operated by mid-1959, and production was confined to

Digitized by Google

a few tons of hand-sorted direct shipping ore. When Russian technicians took over, new pumping and precipitation tanks were installed without consideration of the total shortage of scrap iron. In 1961 the pumps broke down and all underground workings were flooded. Production since then, amounting to only about 350 tons in 1963, has been from small pit operations.

Iron and Steel.—The abundant iron ores of Cuba vary widely in quality and are metallurgically complex. With virtually no market demand, production and exports have dwindled to very small quantities.

Cuba has no smelting plant, though one has been promised by the U.S.S.R. Three secondary plants in the Province of Havana have the combined capacity to produce 25,000 tons of pig iron, 170,000 tons of concrete reinforcing rods, and 20,000 tons of cast iron pipe annually, using scrap and imported pig iron, billets, ferrosilicon, and fluorspar. Actual production in 1958 was 3,500 tons of pig iron, 64,000 tons of reinforcing rod, and 4,500 tons of pipe, representing an estimated 100, 39, and 15 percent, respectively, of the apparent consumption of those items, and, collectively, 25 percent of the total consumption of iron and steel products and manufactured items, which amounted to 292,300 tons in that year. About 16,200 tons of imported bars, rods, plates, and sheets (including tinplate) was consumed by hundreds of small foundries, machine shops, and workshops for the manufacture of such items as window frames, doors and door frames, grates, pipe fittings, iron furniture, heaters, ovens, and kitchen utensils. No statistical measure of change in this pattern has been received since the overall nationalization of 1961, but the United States and Western European sources of imports have been displaced by Eastern European Communist countries, and much of the foundry activity is now devoted to the fabrication of machinery parts for broken and worn out factory, plant, and automotive equipment.

Manganese.—Cuba has never had an internal market for manganese ore but has been a producer and exporter of metallurgical grade since 1888 and of chemical grade since 1945. Peak output in both categories was reached at the height of the Korean conflict in 1953 with a 353,218 metric ton export total comprised of 341,699 tons of metallurgical and 11,519 tons of chemical grades. Total production then declined gradually to 234,050 tons in 1956, and abruptly to 134,514 tons in 1957 and 74,339 tons in 1958, under the combined influences of a weak market, increased competition from Brazil, and (since 1956) political instability. Manganese deposits are known in five of the six provinces of Cuba, but except for an insignificant tonnage from Pinar del Rio, Oriente has been the only effective producing province in recent years. The Charco Redondo mine of Cía. Minero Turquino, S.A., a Cuban company (Francisco Cajigas and Associates), has been—and the property still is—the predominant producer, yielding metallurgical-grade ore exclusively. The remaining 10 to 15 percent of the metallurgical grade ore output has been supplied by some 30 to 50 small mines which also yield all of the chemical-grade ore. They were formerly controlled by United States, Canadian, and private Cuban capital. A few of the mines, notably Charco Redondo and Montenegro, have shipped part of their ore direct, without concentra-

Digitized by Google

tion. The great majority, however, requires total concentration, in some cases by log washer, screen or classifier, but generally by jigs. The ore may be so treated at the mine where it is produced or sent to a centrally located plant treating ore from several mines. All the ore was sold in the United States, which favored Cuba and the Philippines by permitting manganese imports from those countries to enter duty free. The last United States imports from Cuba were in 1960. Shipments since have been to the Communist countries.

In January 1959 Charco Redondo was the first mine property in Cuba to be confiscated and placed under the operation of an "interventor." Later it was renamed Harlem. By the end of 1960, all other properties had similarly entered the domain of the state. Production dropped abruptly but quickly recovered, and in 1963 surpassed that of 1958. Production in 1963 of ore upgraded for shipment has been estimated in metric tons as follows, based on the mid-year rate:

Mine or mine group	Metallurgical-grade ore		Chemical-grade ore (91 percent MnO_2) (metric tons)	Total (metric tons)
	Quantity (metric tons)	Manganese content (percent)		
Harlem (ex-Cía. Minero Turquino, S.A.)	[1] 63,636	48	----------	[1] 63,636
El Cristo (ex.Holston Trading Corp.)	4,517	41	80	4,597
Bueycito (ex.-Holston Trading Corp.)	377	44	1,669	2,046
Margarita de Cambute (ex-Inter-American Industries, Inc.)	71	44	1,307	1,378
Ponupo (ex-Cía. Firmeza, S.A.-Felipe Godoy)	3,815	39	208	4,023
Total shipping ore	[1] 72,416	39 to 48	3,264	[1] 75,680

[1] Includes 1,557 tons of direct shipping ore, metallurgical grade, 40 percent manganese.

Much of the upgrading apparently was done at the reactivated nodulizing plant at the port formerly known as Felton and now renamed Porfirio Hechavarria Santos. This plant, previously owned by Bethlehem Mines Iron Co. for nodulizing lateritic iron ore, had been unsuccessful and in disuse for some time. It was converted in 1960 to treat low-grade manganese ores hauled by truck at prohibitive cost from the Harlem (Charco Redondo) mine. Output dropped from 67,000 tons in 1961 to 55,148 tons in 1962 when concentration equipment was installed at Harlem and possibly reactivated elsewhere. A large new concentrating and sintering plant of 1,000-ton daily capacity at Santiago de Cuba was scheduled to start operating in 1962, by which time a stockpile of more than 50,000 tons of sub-grade ore had accumulated there. The three-unit sintering plant was badly damaged by foundation failure shortly after its inauguration on July 26, 1960, and whether any of its units have resumed operation is not known.

Nickel and Cobalt.—Nickel production, the largest mineral industry in Cuba, was developed in Oriente Province by two United States enterprises before 1958.

The oldest and only operation which attained important output was the U.S. Government project at Levisa Bay, operated on a fee basis between December 1943 and March 1947, by the Nicaro Nickel Co., a subsidiary of Freeport Sulphur Co., and from January 1952 to

Digitized by Google

October 24, 1960, by the Nickel Processing Corp., owned 60 percent by the National Lead Co. and 40 percent by Formento de Minerales Cubanos, S.A., a Cuban company. From more than 15 million tons of laterite ore treated during those two periods, the project produced nearly 198,000 tons of oxide containing 158,386 metric tons of nickel, including a minor content of cobalt. The cobalt could not be separated and was counted commercially as the equivalent of nickel until 1958, when the demand for nickel of higher purity reacted adversely on marketability of the Cuban product. Production from September 20, 1960, when an unsuccessful attempt was made to suspend operations, to October 24 when the properties were confiscated—and for the remainder of the year—has not been reported, but is supposed to have been included with the production tonnage reported for 1961. At the time of confiscation, the physical plant, including all properties, equipment, inventories, cash, and stocks, was valued at US$100 million. The detailed history of the operation as a U.S. Government project, from its inception, has been published.[4] The Cubans renamed the Nicaro plant Comandante Rene Ramos Latour. On November 29, 1960, a team of Russian technicians arrived to help the Cubans run the plant, and the U.S.S.R. has supported the project technologically, materially, and financially ever since. In 1963 operations reportedly were under the direction of 16 Soviet, 4 Czech, and 4 Latin engineers. A process for producing electrolytic nickel from Cuban oxide has been adopted by Czechoslovakia's Sered works, the only nickel producer in Central Europe.

The Moa Bay Mining Co., a subsidiary of the Freeport Sulphur Co., started development of a nickel-cobalt project in a mining area some 50 or 60 miles east of Nicaro in 1954. Two ultramodern plants were built to perform a special leaching process developed by Freeport. One was a facility to produce 1,300 tons per day of 98 percent sulfuric acid from liquid sulfur brought in special vessels from Louisiana. The other was a plant to utilize the acid in the production of 125 tons per day of sulfide concentrate in the form of slurry to be piped into the sulfur-carrying vessels for delivery on their return trip to a refinery in Louisiana for final treatment. These plants were placed in operation in December 1959, and between then and mid-1960 made five shipments of slurry containing 3,496 metric tons of solids. Nickel content of the solids was 50 to 55 percent, and the approximate nickel-to-cobalt ratio was 11:1. The Louisiana plant recovered from the slurry, in the form of refined metals, approximately 3,450,000 pounds of nickel and 304,840 pounds of cobalt, representing the total production of the Moa Bay project under private ownership, and the total return on Freeport's $61.5 million investment in Cuba. On August 18, 1960, the Cuban Government took over all company properties and operations in Cuba by "intervention"—a term adopted for confiscation or seizure. The leaching plant and the Louisiana refinery were designed as interdependent units of the total processing procedure, and the Cubans were unable to overcome the technical difficulties governing utilization of the plant until 1962. This was then at least partially accomplished with the aid of Russian, Czech, Polish

[4] Closedown and current status of U.S. Government nickel plant at Nicaro, Cuba. Hearing before a Subcommittee of the Committee on Government Operations, House of Representatives, Eighty-Seventh Congress, First Session, Aug. 29–30, 1961.

Digitized by Google

and other foreign engineers, Cubans trained in the U.S.S.R., and material and financial support from the U.S.S.R. and other European Communist nations. In 1963, at Moa Bay, renamed Bahia Minera Comandante Pedro Soto Alba, the engineering staff reportedly included two from the U.S.S.R., two from Chile, one from Argentina, one from Spain via the U.S.S.R., and four Cubans recently returned from training in the U.S.S.R.. Production in 1963 was only 14 percent of the annual output planned by Freeport, but officials claim that operations have been largely experimental and that production should exceed that of Rene Ramos Latour (Nicaro) in 1965.

Plans for the future are said to include immediate construction of a small ammonia plant to relieve the U.S.S.R. of its supply burden, ultimate substitution of either an ammonium carbonate or an electrolytic process to eliminate the sulfur precipitation plant at Pedro Sota Alba (Moa), and a new Czech-supplied cobalt plant and $100 million nickel plant at Rene Ramos Latour to produce refined metal. Whether the nickel and cobalt are now being separated from Cuban concentrates and separately refined in Europe is not known.

NONMETALS

Pyrite.—The 1963 output of pyrite was primarily the 32,544-ton production of a property operated by or named for one Julio A. Mella. This probably is the Mono mine, but could be any one of the following three:

Mono, 3 kilometers northeast of Matahambre in the Province of Pinar del Rio, was drilled by Cía. Minera Inspiracion Occidental, a subsidiary of Minas de Matahambre. A reserve conservatively estimated at 1 million tons of hard, massive, fine-grained pyrite was developed, containing 43 percent sulfur, 2.4 percent lead, 5.2 percent zinc, 0.17 percent copper, 0.19 ounces of gold per ton, and 2.2 ounces of silver per ton. To utilize this ore a US$10 million plant was completed at Santa Lucia in 1960, designed to produce 300 tons of sulfuric acid per day and to recover from the calcine copper, lead, gold, and silver values by means of a chloridizing roast and acid leaching.

Antonio, 16 kilometers northeast of Fomento, Province of Las Villas, produced 63,053 tons of pyrite containing 944 tons of copper in 1956–57. Sales were to Europe. Indicated reserves at the time it was closed down were at least 50,000 tons.

Carlota, 9 kilometers southeast of Cumanayagua, which is east of Cienfuegos, Province of Las Villas, last produced in 1921 and was last examined in 1951–52 by the Freeport Sulphur Co. Reserves are large but low in copper.

The remaining 1,167 tons of 1963 pyrite production is credited to the Buenavista mine, 12 kilometers east of Bahía Honda, Province of Pinar del Rio. This is a copper mine traditionally producing chalcopyrite in a massive pyrite containing 4 to 5 percent copper, but with no copper production mentioned in 1963. It may be that the mine has ceased to operate, and that pyrite production was from tailings dumps only.

The Margot mine in the Province of Matanzas produced and shipped to Europe 350,000 tons of pyrite containing 944 tons of copper in 1952–57, but then closed down when reserves were exhausted.

MINERAL FUELS

Half of the total energy requirements of Cuba for 1955–59 was supplied by domestic bagasse and fuel wood, and half by petroleum, of which 97.6 percent of the crude and 43.2 percent of the refinery products were imported. Yearly averages for the period were—

	Quantity (thousand barrels)
Runs to stills:	
Domestic crude (including natural naphtha)	369
Imported crude	14,957
Total crude refined in Cuba	15,326
Refined products:	
From refineries in Cuba	14,022
Imported	10,651
Total refined products available	24,673
Exported (est.)	4,700
Approximate refined products consumed	20,000

Activities in the industry during the period had none of the uniformity suggested by the averages. Domestic production of crude rose from 369,000 barrels in 1955 to 543,000 barrels in 1956, and declined steadily to 192,000 barrels in 1959. Crude imports rose abruptly from 3.6 million and 3.9 million barrels, respectively, in 1955 and 1956, to 25.8 million and 26.4 million barrels, respectively, in 1958 and 1959. Domestic refinery output and imports of refinery products followed a parallel and reverse pattern, respectively, but the decline in imports was more moderate. Requirements for refinery products as measured by approximate consumption rose steadily from about 15 million to 28 million barrels. Domestic refinery production declined in 1960 and 1961, but recovered to the 1959 level by 1963. If exports have stopped, which appears likely, Cuban consumption in 1963 should have been in the order of 30 million barrels.

Domestic production of crude in 1958 and 1959 was from three old fields pumping or bailing from accumulations in shattered pockets in serpentine, and from new fields yielding oil from sedimentary rock reservoirs, as follows:

Field	Province	First production	Petroleum type	Production, barrels	
				1958	1959
From serpentine:					
Bucuransa-Cruz Verde	Havana	1914 to 1956	Paraffin	53,329	22,085
Motembo	Las Villas	1934	Naphtha	3,435	2,995
Jarahueca	Las Villas	1943	Paraffin	23,997	9,475
From sedimentaries:					
Jatibenico	Camagüey	1954	Asphalt	211,453	136,254
Santa María del Mar	Havana	1956	Paraffin and asphalt.	10,863	9,095
Catalina	Camagüey	1956	Paraffin	4,552	----------
Guanabo	Havana	1956	Asphalt	35,903	14,943
Total				343,532	194,847

Digitized by Google

Following drastic revisions of the petroleum law in 1959, all private exploration activity came to a halt and the Cuban Gulf Oil Co., Atlantic Refining Co., and Cuba California Oil Co. closed their offices. A dozen years of disappointing exploration had cost them more than US$30 million. Since then exploration has been renewed by Soviet technicians with no discoveries reported.

There were eight refineries in Cuba, listed according to ownership, location, and daily distillation capacities exclusive of other processing units, as of the beginning of 1959:

		Barrels
Esso Standard Oil Co., S.A.	Belot, Havana	36,500
Cía. Petrolera Shell de Cuba, S.A.	Havana, Havana	27,000
The Texas Co. (West Indies) Ltd.	Santiago de Cuba, Oriente	20,000
Refineria Cabaiguán	Cabaiguán, Las Villas	2,500
Corporacion General de Petroleo	Jatibanico, Camagüey	1,000
Santa Maria Oil Refining Co	Cotorro, Havana	600
Bucuranao Refining Co	Bucuranao, Havana	300
Petrolera Jarahueca, S.A.	Jarahueca, Las Villas	200
Total daily crude distillation capacity, barrels		88,100

On June 29 and July 1, 1960, the foreign-owned refineries of Esso Standard, Shell, and the Texas Co., representing 94.8 percent of the refining capacity of the country, were seized by the Government after refusing to process Soviet crude in displacement of crudes customarily imported from Venezuela. The Cabaiguán refinery had been confiscated earlier in 1959 because its operators were not in sympathy with the Communist regime. The remaining refineries were later brought under national control of the Cuban Petroleum Institute, and the Soviets are said to have agreed to expand refining facilities.

The Mineral Industry of the Dominican Republic

By Sumner M. Anderson [1]

IN 1963 the Dominican Republic produced 2.6 percent of the world's production of bauxite and 4.9 percent of that produced in the Western Hemisphere. It ranked fourth among the six bauxite producing countries in the Latin American area, and one of three that registered a production increase over 1962.

Agriculture normally yields over 80 percent of the country's foreign exchange earnings and 41 percent of the gross national product (GNP) as measured in 1958. Trade in that year accounted for 17 percent of the GNP; manufacturing 15 percent; government 7 percent; and other activities 20 percent, of which about 2 percent was supplied by the mineral industry.

The nonarable Cordillera Central, the highest mountain range in the Antilles, extends in a southeasterly direction through the center of the country. There are no inland waterways of any importance. The capital and principal port of Santo Domingo on the Caribbean Sea (south coast), handles about 90 percent of the imports and 40 percent of the exports. Transportation is mainly by highways of varying adequacy which connect most of the important towns, but there is a shortage of feeder roads.

The industrial census for 1961 showed that mining and manufacturing of mineral and metal products employed 3,859 persons, distributed as follows:

SOURCE MATERIAL

Production statistics for 1959–61 are from Estadistica Industrial de la República Dominicana, No. 12, 1961, published in 1963 by the Dirección General de Estadistica y Censos, Santo Domingo. Production data for 1962 and 1963 and much of the description of individual segments of the industry were supplied by the U.S. Embassy, Santo Domingo, from industrial sources and the following Dominican Government sources: Dirección General de Minería, Ministerio de Industria y Comercio; Banco Central de la República Dominicana (bauxite); and Corporación de Fomento, the Government agency which administers Sal y Yeso Dominicano (mined salt and gypsum) and Fabrica Dominicana de Cemento (cement).

Trade statistics are from Comercio Exterior de la República Dominicana, v. IX, 1961, and v. XI, 1962, Dirección General de Estadistica y Censos. General economic data were abstracted principally from "Summary of Basic Data" releases prepared by the Agency for International Development.

Supplemental information on the bauxite and iron ore deposits was derived from the following publications: Goldich, S. S., and Berquist, H. R., Aluminous lateritic soil of the Sierra de Bahoruco area, Dominican Republic, W.I., United States Geological Survey Bulletin 953–C, 1947, pp. 53–84; and Kochman, A. H., and Gordon, Mackenzie, Jr., Geology and mineral resources of the Maimón-Hatillo district, Dominican Republic, United States Geological Survey Bulletin 964–D, 1950, pp. 307–357.

Digitized by Google

PRODUCTION

Bauxite production in 1963 was the highest since the start of operations in 1959. Other reported extractive segments of the industry were sharply depressed. In 1961, the latest year for which value figures are available, the value of total mineral production was estimated as US$17,825,000, representing 2.7 percent of that year's GNP of US$660,400,000.

The Dominican Republic is self-sufficient in its requirements for salt, gypsum, limestone, gray cement, lime, granite, and sand, and virtually so for clay.

TRADE

The Dominican Republic has no facilities for processing bauxite beyond crushing and drying and exports all it produces. It exports quantities of domestically produced gypsum, salt, gray cement, dimension stone, amber, aluminum manufactures, and ceramic products that are beyond its own requirements. The Republic is dependent on imports for all of its required metals and alloys, white cement, and mineral fuels, most of its metallic semimanufactures and finished goods, and some glass and ceramic specialties.

Metal and mineral manufactures, which have not been included in other country chapters, have been included in the foreign trade statistics for the Dominican Republic for reasons of comparability, inasmuch as they are not statistically separable from some of the metal groupings reported.

Digitized by Google

The dollar values shown in the trade tables are equivalent to Dominican Republic peso (RD$) values, which are pegged to the United States dollar at an exchange rate of 1 : 1.

COMMODITY REVIEW

METALS

Bauxite.—Bauxite is the most important mineral product of the Dominican Republic, representing in dollar value 80.4 percent of mineral exports, 5.1 percent of total exports, and 1.1 percent of the GNP in 1962. Alcoa Exploration Company, a subsidiary of the Aluminum Company of America and the sole producer, started shipments in early 1959 following 7 years of exploration and the investment of $14 million in mine development and equipment and the construction of port facilities. An appreciable portion of this investment went into construction of a pier 2,100 feet long and 440 feet wide at Cabo Rojo on the south coast adjoining Haiti, where no national harbor exists; the pier has been subjected twice (1955 and 1956) to severe hurricane damage.

The bauxite zone is about 32 kilometers in from the coast and contains a series of valley or basin type deposits on the southwestern slope of the Sierra da Bahoruco in the southwestern Provinces of Barahona and Pedernales. Within its concession of 8,783 hectares, Alcoa has been operating the Aceitillar mine, 4,300 feet above the level of the sea in Pedernales Province. The bauxite contains, as shipped, close to 50 percent alumina, 3 percent silica, and 18 percent moisture, which is more or less typical of that found elsewhere in the bauxite belt extending westward through southern Haiti and Jamaica. It is mined by power shovel and trucked in 28- to 32-ton loads about 34 kilometers to a 60,000-ton storage area at the Cabo Rojo wharf, from which it can be belt-loaded into vessels at a rate of 1,250 tons per hour for shipment to Alcoa's alumina plant at Point Comfort, Tex., via the port of Aransas Pass. The company's facilities in the Dominican Republic are large enough to mine and ship 1 million tons of ore per year.

Gold.—Dominican gold has been the product of hand panning by thousands of men, many of whom are only part-time miners. Mountain streams in five provinces have yielded gold, but all production in 1960 and possibly since has been from the Provinces of Seibo and Santiago Rodriguez only, principally from concessions granted in 1960 to Cardox Dominicana, C. por A. Coarse flake gold placers discovered in 1958 on the Mao and Bulla Rivers near the village of Bulla in Santiago Rodriguez were reportedly large enough to justify the adaption of mechanized recovery methods, but there is no evidence that this has been done. Production since 1960 has not been officially reported. Activity in Seibo for many years has been in and around the north coast port of Miches, near the eastern end of the island.

Iron Ore.—Relatively small but high grade pockets of magnetite and lateritic hematite occur in the Maimón-Hatillo iron ore district, an area roughly 25 kilometers long and 17 kilometers wide near the center of the country in Sanchez Ramirez and La Vega Provinces. These deposits yielded a total of 869,812 metric tons of ore from 1952 through 1960. Production apparently ceased in 1960, as none has been reported since that time; 13 tons of iron ore exported in 1961 is believed to have been mined in 1960.

A 30-year mining concession for the area was granted to Explotación Minera Hatillo, C. por A., on July 6, 1949, and was extended

Digitized by Google

for an additional period of 10 years in 1952. This Government-controlled company did some exploratory mining and installed a small pilot mill before negotiating a series of operating concessions with three private companies. Cía. Minera Dominicana, C. por A., worked the deposits from early 1952 to April 1953, and Cía Minera Panamericana, C. por A., worked them from April 1953 to September 1954; these two companies produced a total of 217,366 metric tons of ore. Cía. Dominicana de Minerales, C. por A., a subsidiary of Phoenix Iron and Steel Co. (operating arm of Barium Steel Co.), produced 529,701 metric tons of ore between January 1, 1955, and May 31, 1959. Explotación Minera Hatillo, C. por A., then undertook mining on its own account late in 1959 and produced 122,745 tons of ore by late 1960. The company apparently did not complete a contract to supply 25,000 tons of ore per month for 3 years to Ferrostaal Import-Export Corp. of Essen, West Germany, and it may be assumed that known reserves of commercial ore were exhausted.

Most of the ore mined was high-grade (66–68 percent iron) lump of open-hearth quality. The deposits were covered by only a few feet of overburden, and the ore was extracted with power shovels. After being washed, it was trucked 105 kilometers to the Rio Haina docks near Santo Domingo (then called Ciudad Trujillo) for export, mainly to the United States.

Iron and Steel.—The National Armory at San Cristobal, about 26 kilometers west of Santo Domingo, is the largest and most important element of the small Dominican iron and steel industry, which also includes four smaller foundries in the Federal District, two in San Pedro de Macoris Province, and one each in Barahona and San Cristobal Provinces.

Servicos Technologico, a branch of the Department of State for Armed Forces, manufactures arms and military equipment at the Armory, utilizing domestic scrap and imported pig iron and coke. In 1953 or 1954, the plant began to use part of its productive capacity to manufacture commercial and industrial products, and became the only producer of cast iron pressure pipe and fittings in the Dominican Republic.

Quantity of pipe production has not been reported since 1956 when the output was estimated as 540 metric tons of 4-meter lengths of 4-, 5-, 6-, and 8-inch diameter pipe and accessory fittings. Principal customers for this pipe are the contractors who install secondary lines on Government-owned water distribution systems and the sugar and oil companies; a small market also exists in private housing. Degree of self-sufficiency cannot be calculated because official import statistics do not separate pressure pipe from the larger category which includes all cast iron pipe, fittings, and such accessories as valves, drains, and plugs.

NONMETALS

Gypsum and Salt.—The great gypsum and salt deposits about 40 kilometers west of the port of Barahona, lie parallel to each other in the same geologic sequence, forming a range of hills about 11 kilometers long. Reserves reportedly include at least 1,000 million tons of gypsum and 250 million tons of readily accessible salt. In 1956, the Gov-

Digitized by Google

ernment Agricultural and Industrial Credit Bank, sold the gypsum and salt concession to Sal y Yeso Dominicanos, C. por A. After the 1961 political upheaval, the properties were confiscated by the new Dominican Government. They were operated again by the Agricultural Bank and, since March 1963, by the Industrial Development Corporation (Corporación de Fomento) at two open-pit mines. The salt mine is at Las Salinas, 6.4 kilometers west of the gypsum mine.

Both mine products, after grinding and screening, are hauled by narrow-gage railway to the dock area in Barahona, from where they are exported, except for the gypsum requirements of the Government-owned cement plant in Santo Domingo and a small quantity of salt refined in Santo Domingo for table use. The Industrial Development Corporation also recovers salt from sea water in solar evaporation salinas at Puerto Hermosa, Las Calderas Bay, on the south coast between Barahona and Santo Domingo.

Gypsum and salt, respectively, are the third and fourth most valuable mineral products of the Dominican Republic, following bauxite and cement, but production has declined sharply since the 1961 transfer of operations to the Government.

MINERAL FUELS

Petroleum.—Petrolera Dominicana, C. por A., which had U.S. capital, suspended petroleum exploration in the first half of 1961, and there has been none since. On March 26, 1963, a contract signed the previous August between the Dominican Government and Esso Standard Oil Co. providing for the construction of a petroleum refinery in the Dominican Republic was rescinded by mutual agreement. The Government showed continued interest in establishing a refinery, but by the end of the year nothing further had developed beyond discussions. All of the Republic's mineral fuel needs are imported.

The Mineral Industry of Haiti

By Sumner M. Anderson [1]

HAITI is significant in the world mineral economy only as a relatively minor producer of bauxite and copper. These items however, provide an important share of the domestic economy, supplying collectively about 23 percent of the gross national product (GNP) of a country whose GNP per capita (US$71 in 1961) is the lowest in Latin America. Haiti is essentially self-sufficient in the production of limestone, lime, cement, and salt; the relatively small quantities of all other commercial metals and minerals, mineral products, and mineral fuels required for the economy are imported. The mineral industries are financed by investment capital from the United States in bauxite, from the United States and Canada in copper, and from France, Haiti, and Venezuela in cement. Local individuals and small groups engage in the production of lime, limestone other than for cement manufacture, and salt. Mineral exploration is in process, but small known deposits of antimony, gold and silver, iron, nickel, tin, gypsum, sulfur, and coal are undeveloped. Petroleum exploration has not been successful.

The 4,431,000 (1963) French- and Creole-speaking inhabitants of Haiti are crowded into the 10,700 square miles that comprise the western third of the island of Hispaniola, giving Haiti the highest population density in Latin America, with 414 per square mile; annual population growth is 2.1 percent. The economy is based primarily on agriculture, which engages 83 percent of the labor force. Five percent are employed in manufacturing (including cement) and construction, and 12 percent are employed in other activities including mining and government service.

PRODUCTION

The Haitian Government does not provide definitive statistics on mineral production. The data on production of bauxite, copper, and cement were provided by the various companies. Those for lime, limestone, and salt were provided by the U.S. Embassy in Port-au-Prince as representing the best available estimates.

[2] Estimated annual average.

TRADE

The statistics on metal and mineral trade are those officially published on a fiscal-year basis in Importations et Exportations, Années Fiscales 1960–61, 1961–62, by the Administration Générale des Douanes, Port-au-Prince.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1960–61 [1] (quantity)	1961–62 [1]		
		Quantity	Principal destinations	Value (gourdes) [2]
Metals:				
Aluminum ore, bauxite	352,930	451,329	All to United States	18,343,185
Copper concentrate	7,505	18,398	Japan 15,286; Portugal 3,112	16,190,101
Total:				
Value of metal exports				[3] 34,533,286
Value of all exports				[4] 204,162,446
Metals share in total exports percent				16.9

[1] Fiscal year, ending Sept. 30.
[2] 1 gourde = US$0.20.
[3] US$6,906,687.
[4] US$40,832,489.

TABLE 3.—Imports of metals and minerals in 1960–61 [1]

(Metric tons unless otherwise specified)

Commodity	Quantity	Principal sources	Value (gourdes) [2]
Metals:			
Aluminum alloys, unmanufactured.	28	Switzerland 15; United States 4; Austria 4.	156,518
Copper and copper alloys, unmanufactured.	103	United States 44; Belgium 19; United Kingdom 18.	666,111
Iron and steel:			
Cast iron pipes, tubes, fittings.	436	France 98; West Germany 89; United Kingdom 60.	582,227
Steel:			
Bars, rounds, etc.	2,380	Belgium 858; France 694; Luxembourg 327.	1,577,974
Plates, sheets, strips and bands, uncoated.	309	Belgium 168; United States 74; Luxembourg 40.	281,045

COMMODITY REVIEW

METALS

Bauxite.—Deposits of bauxite are in the southern peninsula, in the east-west bauxite belt which includes similar deposits in Jamaica and southwestern Dominican Republic. Deposits near Beaumont and Savane Zombi (and near Gonaïves in the northern part of the country) are too thin and low in grade to be commercially valuable. The largest operational deposit is in the Rochelois Plateau at an elevation of 956 meters (3,100 feet) at Sainte Croix and is up to 30 feet thick. From March 1957 to the end of 1963, Reynolds Haitian Mines, Inc. (the corporate name under which Reynolds Metals Co. of Richmond, Va., operates in Haiti), mined approximately 2,059,000 metric tons of bauxite (calculated to a moisture-free basis) from this deposit. At least 8 million tons of recoverable ore remained in reserve. The ore is crushed and dried at the mine site and hauled approximately 19 kilometers (12 miles) in 30-ton trucks to the port of Miragoâne, where a loading pier has been constructed. Shipments reported in "long dry tons" carried an average 13.4 percent moisture. The ore has been shipped to the company's refining plant at Corpus Christi, Tex., which is specially designed to process Jamaican and Haitian ores. Damage to the port facilities at Miragoâne by Hurricane Flora on October 3, 1963, may have contributed slightly to that year's production drop but shipping was not seriously interrupted. The company continued to provide free electricity to the port of Mirogoâne and to maintain a private hospital. Relationships with the Haitian people reportedly are excellent.

Copper.—An area of 25,000 hectares (96.5 square miles) in the Terre Neuve district, Department of L'Artibonite, 24 kilometers (15 miles) north of Gonaïves, was explored intensively in 1956–58 by SEDREN S.A. (Société d'Exploitation et de Développement Economique et Naturel d'Haiti), a subsidiary of the United States-Canadian financed Consolidated Halliwell Ltd. of Toronto. Tunneling and more than 70,000 feet of diamond drilling developed an estimated 5,200,000 tons of 1.7 percent copper ore, including 1,800,000 tons of 2.5 percent copper in the Meme ore body. The ore is in metamorphic deposits along a contact of Upper Eocene limestone with intrusive quartz diorite, with veins in quartz diorites, basalts, and andesites. Chalcopyrite is the principal copper mineral and is associated with bornite in the enriched veins. The company then installed mining equipment; sank shafts; drove adits; built a concentrating mill with a capacity of 1,500 tons per day, a 25-million-gallon reservoir to insure a water supply, roads, and dock facilities at the port of Gonaïves; and undertook the training of Haitian labor. Total plant operations began in October 1960, and from then to the end of 1963, production was 47,700 metric tons of concentrate containing 16,400 tons of copper. The concentrate was shipped to Minerals and Chemicals Philipp Corp. in the United States, but at a rate far short of the ultimate goal of 32,650 metric tons annually. As of the end of 1960, the company was employing about 500 Haitians. SEDREN has a 25-year exclusive concession from the Haitian Government granted in April 1955.

NONMETALS

Cement.—Le Ciment d'Haiti, a company capitalized at US$1,250,000 by the French owners of Compagnie des Grands Travaux de Marseilles, the Haitian Bank for Industrial and Agricultural Credit, and private Haitian and Venezuelan investors, has manufactured cement since mid-1954. The wet-process plant, using a single diesel-fired kiln with a capacity of 150 metric tons per day, is on the coast at Source Matelas, about 24 kilometers (15 miles) north of Port-au-Prince and adjacent to large deposits of marl. The company also constructed a wharf at the port for ocean shipments, but has been unable to produce for export a surplus over the domestic requirements of the building and construction trades. Cement imports, however, which formerly supplied the total needs of the country, have been reduced to a few hundred tons per year. In addition to manufacturing cement, the plant casts concrete blocks and other forms for construction, and crushes limestone for sale in uncalcined form.

No information is available on lime, except that it has been produced in small, old-fashioned, and generally handmade kilns which are numerous and widely scattered.

Salt.—No accurate figures on salt production can be obtained because of the diversity of the producing areas and their small size. Individual peasants and small groups flood rectangular lowland areas with sea water, which is left to dry in the sun; the remaining salts are then harvested and marketed throughout the country. Analyses of the product made in 1948 showed only 87 percent sodium chloride, 10 percent salts of calcium, magnesium, and potassium, and nearly 3 percent dirt. It is not known if the quality of the product has improved since that time. In any event, it serves the predominant needs of the nation; less than 100 tons of refined salt have been imported annually.

MINERAL FUELS

Petroleum.—Haiti is not a petroleum-producing country, and sizable capital invested in petroleum exploration yielded negative results. Petroleum refinery products imported for Haitian consumption are distributed through marketing outlets maintained by the Esso, Texaco, Sinclair, and Shell companies or their affiliates.

On February 14, 1963, the Haitian Government published the constitutive act and statutes of the Haitian Petroleum and Refining Co. and announced official approval of that company's Valentine refinery project. The company was capitalized at $100,000, of which more than half was paid in at that time. The president and most of the principal officers are residents of the United States. Surveys were started in the Port-au-Prince area for a refinery site, but at year end there was no evidence that the project had progressed beyond that point.

The Mineral Industry of Jamaica

By Garn A. Rynearson [1]

ALTHOUGH Jamaica's mineral industry is limited to the production of only a few mineral commodities; this small Caribbean island of only 4,411 square miles is the world's foremost producer of bauxite and a significant producer of alumina. Jamaican bauxite output surpassed that of Surinam in 1957 and has led that of all countries ever since. Output in 1963 was slightly more than 23 percent of the world total. Approximately three-fourths of the bauxite mined in Jamaica is exported to the United States, where it constitutes more than half of the annual supply, and one-fourth is converted to alumina for export. Jamaican output of limestone, gypsum, clay, and other construction materials is of significance mainly to the domestic economy. Appreciable quantities of gypsum are exported to the United States, and large reserves of high-grade material may enable Jamaica to become a more important exporter of this commodity in the future.

Jamaica's mineral industry, dominated by the production and export of bauxite and alumina, accounts for approximately 10 percent of the country's gross domestic product, which amounted to US$728 million [2] in 1962. National account estimates are not available for 1962 or 1963, but in 1961 mining contributed 8.9 percent of the total compared with 13.4 percent by manufacturing, 13.0 percent by agriculture, forestry, and fishing, and 11.5 percent by construction and installation; cement manufactured contributed about 1 percent. The total market value of Jamaica's mineral products, including cement and lime, probably is in the order of US$90 million annually.

The importance of the mineral industry to the national economy is measured largely by the income derived from the bauxite-alumina operations. Taxes and royalties collected from the bauxite companies constitute the largest single source of Government revenue and represented 15.6 and 10.9 percent of the total revenue for 1962 and 1963, respectively. As the amount of revenue collected is based on a formula that takes into account the price of aluminum pig on the New York market, the low price that prevailed during most of 1963 resulted in considerably less revenue than that collected in 1961 when less bauxite was exported. During 1962 and 1963 the bauxite-alumina industry employed an average of 5,600 persons and had an annual wage bill

that exceeded US$11 million. Other disbursements in the country (that is, capital expenditure, materials and supplies, and services) averaged US$15 million.

SOURCE MATERIAL

This report is based mainly on official publications by several agencies of the Government of Jamaica and unclassified despatches from the U.S. Embassy at Kingston. Supplemental information pertaining to specific commodities was derived from other published sources. Among these were a series of articles by Mike Eigo, published in the January, March and May 1964 issues of Engineering and Mining Journal, which describe in detail the bauxite and alumina industry of Jamaica as of the latter part of 1963. Information on iron was derived, in part, from an article by V. G. Hill on investigations made by the Scientific Research Council of Jamaica, published by the United Nations (E/Conf. 39/A384, November 1962, 8 pp.), and part of the information on petroleum refining was derived from an article by W. B. Hudson in the February 1964 issue of World Petroleum.

PRODUCTION

Overall output of Jamaica's mineral industry during 1963 remained at about the same level as in 1962. A substantial decrease in bauxite production for export, reflecting the general decline in world demand, was partly offset by a record output of alumina. Gypsum output rose slightly despite the large stocks (291,088 metric tons) carried over from 1962. Cement output also increased slightly but was considerably lower than in 1960 and 1961. The lag in both public and private construction activities during 1962 and the first half of 1963 has been attributed largely to an attitude of caution that prevailed while the Government of the newly independent nation was becoming established. This attitude apparently has changed to one of optimism; a marked increase in construction was noted in the latter part of 1963. It is expected, therefore, that during 1964 production of cement and other construction materials will return to normal levels.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Aluminum:					
Bauxite mined, dried equivalent	[2] 5,208,047	5,836,994	6,770,063	7,615,419	7,013,910
Alumina (exports)	405,617	676,040	714,774	637,719	737,193
Nonmetals:					
Cement, common portland	195,617	212,175	215,710	200,162	200,721
Glass sand	(3)	(3)	(3)	6,648	(3)
Gypsum	475,668	249,778	226,625	228,923	231,968
Limestone	(3)	(3)	(3)	[4] 1,708,000	(3)
Phosphates	35	65	68	57	14

[1] In addition to commodities tabulated, Jamaica produces china and pottery clays, lime, marble, and clay, sand, and gravel for construction purposes, but data on quantities are not available.
[2] Revised figure, supersedes that given in commodity chapter, volume 1.
[3] Data not available.
[4] Based on officially estimated production of registered quarries.

TRADE

Three commodities—bauxite, alumina, and sugar—comprise 75 percent of Jamaica's total exports. The combined export value of bauxite and alumina, measured as a portion of total domestic export value, declined from 51.0 percent in 1961 to 48.4 percent in 1962 and to 41.8 percent in 1963. Despite the net decline in bauxite-alumina exports during 1963, Jamaica's traditionally adverse balance in visible trade was reduced to US$22.7 million, the lowest deficit since 1954, because of a sharp increase in the value of sugar exports, which accounted for 33.5 percent of the total for the year.

The island's limited natural resources and its relatively small manufacturing capacity cannot provide many of the needs of a domestic market consisting of 1,706,000 Jamaicans and numerous tourist visitors. Almost all capital goods, most durable consumer goods, and a substantial amount of foodstuffs (about 20 percent of all imports) are imported. Although exports of mineral commodities far exceed imports in this category, Jamaica has to import virtually all its metal and mineral fuel requirements and such essential nonmetals as salt, sulfur, and fertilizer materials. The level of these imports has remained fairly stable in recent years. Preliminary data for 1963 indicate that increased imports of metals and fertilizers were partly offset by a decrease in imports of petroleum products, and the net rise was less than 1 percent.

The United States, which displaced the United Kingdom as Jamaica's principal overall trading partner in 1962, generally receives about half of the island's metal and mineral exports but supplies only about 15 percent of its imports in this category, chiefly in the form of fuel and lubricating oils and metal semimanufactures. The U.S. statistical share of such imports is expected to become even smaller because Jamaica has begun to produce petroleum products in its new refinery and a steel mill is planned for the near future.

TABLE 2.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962		
	Quantity	Quantity	Principal destinations	Value (Jamaican pounds) [1]
Total:				
Value of metal and mineral exports [9].				30,786,740
Value of all exports, f.o.b. [9]				62,224,602
Metals and minerals share percent in total exports [9]				49.47

[1] The Jamaican pound (J£) is equivalent to US$2.80 (US$1.00=J£0.357).
[2] Arbitrary value fixed by agreement between the Government and producer-exporters.
[3] Reexports of wrought and unwrought metals in relatively small quantities. Value in 1961, J£31,530.
[4] Less than 1 ton.
[5] Largely reexports of salt, dimension stone, and fertilizer materials. Value in 1961, J£1,102.
[6] Includes natural gas and gases derived from coal and petroleum.
[7] Excludes liquified petroleum gas (LP gas).
[8] Source reports quantities in gravimetric units. Conversion to volumetric units is based on conversion factors in use by U.S. Bureau of Mines.
[9] Excludes reexports.

[1] Jamaican pound is equivalent to US$2.80 (US$1.00=J£0.357).
[2] Data not available.
[3] Less than 1 ton.
[4] Quantities shown probably include paperbacked foils and therefore do not represent actual amount of metal involved.
[5] Total quantity not available. Includes 10 tons of unspecified material and less than 1 ton each of several specified materials.
[6] Includes natural gas and gases derived from coal and petroleum.
[7] Excludes liquefied petroleum gas (LP gas).
[8] Source reports quantities in gravimetric units. Conversion to volumetric units is based on conversion factors in use by U.S. Bureau of Mines.
[9] May include relatively small amounts of other petroleum or coal byproducts.

COMMODITY REVIEW

METALS

Aluminum.—Total production of bauxite in 1963 declined almost 8 percent from the record output of 1962, despite a marked increase in production for consumption in the island's two alumina plants. The net decline is attributed to curtailment of exports by Kaiser Bauxite Co. and Reynolds Jamaica Mines, Ltd., because of reduced demand in their U.S. markets and lower quotas for the barter of Jamaican bauxite in fiscal 1964. Exports of bauxite were 5,244,391 dry metric tons, almost 14 percent less than exports in 1962. However, alumina exports by Alcan Jamaica, Ltd., increased 15.6 percent to 737,302 metric tons. Barring adverse economic conditions, production and export of

Digitized by Google

bauxite should recover in 1964 as the new facilities of Alcoa Minerals of Jamaica, Inc., come into year-round operation.

In June 1963 Alcoa began sending ore from the Woodside mine in Clarendon Parish to its drying plant and port installations at Rocky Point. Shipments to Point Comfort, Tex. commenced in November. Initial production is to be 250,000 to 300,000 tons per year, increasing to 500,000 or 600,00 tons when full-scale operation is attained. Alcoa's facilities feature 85-ton aluminum-body cars for the 18.5-mile rail haul and an aluminium-domed storage structure 300 feet in diameter with a capacity of 67,000 tons of bauxite.

Kaiser Bauxite Co., the largest producer in Jamaica, embarked on a US$30 million, 5-year expansion program to develop a second mining and port installation. The first phase of the program involves an 18-month dredging project to breach the reef at Discovery Bay on the north coast in order to permit entry of 37,600-ton ore ships and other large vessels. The port terminal to be built will include a deepwater pier and drying, screening, storage, and loading facilities with an initial annual capacity of 1.5 million tons, but will be designed for easy and rapid future expansion. Preliminary work was begun on roadbed construction for 10 miles of railway to connect the port with bauxite deposits in St. Ann's and Trelawny Parishes. Location of the rail terminal and initial mining areas was not announced. A possible site in St. Ann requires a longer haul than one in Trelawny, but the latter requires construction of a 1,200-foot bridge over a river gorge 420 feet deep.

Kaiser continued to improve its main operations in St. Elizabeth Parish on the south side of the island. With a fourth kiln in operation at Port Kaiser, the company's annual capacity has been increased by 2 million tons to a total of 6.3 million tons. The company has started to lay heavier rails on its 17-mile railroad and began replacing the old 75-ton steel cars with 84-ton aluminum cars to increase transport capacity.

Alcan Jamaica Ltd. proceeded with modifications at the Kirkvine alumina plant in Manchester Parish and predicted these changes would permit increased output in 1964. This plant and the Ewarton works in St. Catherine Parish provided Alcan with a total rated capacity of about 750,000 tons of alumina in 1963.

Harvey Aluminum of America has been granted a special mining lease on bauxite deposits in St. Catherine Parish, but no mining was done in 1963. Prospecting by the company has indicated the deposits to be high in silica, and their exploitation in the near future appeared uncertain.

Jamaica has no facilities as yet for reducing its bauxite to metal, but plans for such facilities have been tentatively discussed. Unless and until petroleum is found on the island, development of the power required by such a plant would depend entirely on imported fuels; domestic power sources are extremely inadequate.

Iron and Steel.—Jamaica's first steel mill was scheduled for construction by the Caribbean Steel Co., Ltd., during 1964 and should be in operation in 1965. The US$2.5 million mill will have an annual ingot capacity of 30,000 tons and will use scrap, part of which will be obtained locally and part of which will be imported duty free. A

Digitized by Google

rolling mill with a one-shift capacity of 18,000 tons will process ingots into reinforcing bars. Imports of iron and steel bars averaged about 13,000 metric tons annually during 1959–63, and domestic output of these items is expected to save approximately US$1.4 million on foreign exchange per year.

The new steel mill may give some impetus to establishment of a small, integrated iron and steel industry based on scrap iron, local magnetite and hematite ores, and red mud tailings from the alumina plants. The tailings were being stored in case this industry should materialize.

Small replacement bodies of high-grade magnetite and hematite occur in the metamorphic rocks of the Port Royal Mountains and the Blue Mountain Range in Portland, St. Andrew, and St. Catherine Parishes. The deposits are widely scattered and some are too inaccessible to be of economic interest. The only iron-mining lease in effect in 1963 was registered in the name of Mavis Bank Iron Ore, Ltd., which reportedly has been acquired by the Jamaican firm of International Metals, Ltd. The lease includes the Glade-Orchard deposits in the Mavis Bank area of St. Andrew Parish, where trenching and drilling have proved reserves of about 200,000 tons of minable ore. Other investigations have indicated that three black sand deposits on the south coast might yield about 1 million tons of titaniferous magnetite. A blend of black sand concentrate, Mavis Bank ore, and red mud tailings might overcome the problem of a high titanium dioxide content in the black sand and certain handling problems of the tailings, and thus make a mixture suitable for furnace reduction.

Other Metals.—Small deposits of copper, lead, zinc, cobalt, and manganese ores occur at widely scattered localities in Jamaica. Some of these were worked on a small scale during the 19th century but activities in recent years have been restricted to intermittent prospecting. In 1963, 4 companies held 11 prospecting licenses for copper. A geochemical survey of some of the more promising copper-bearing areas was made in 1961 and some diamond drilling and underground exploration have been accomplished since, but the only production appears to have been the small quantity of high-grade ore or concentrates exported in 1961.

Relatively recent explorations at the old Hope mine near Papine in St. Andrew Parish have indicated reserves of some 65,000 tons of proved and 85,000 tons of probable ore averaging 1.7 percent lead and 3.8 percent zinc with 0.21 ounce of silver and 0.06 ounce of gold per ton. No production of ore or concentrates has been reported.

NONMETALS

Cement.—The Caribbean Cement Co., which operates under a monopoly franchise, supplied virtually all of the country's portland cement requirements from its plant at Rockfort in St. Thomas Parish. This company also exported cement to many of the other Caribbean islands. Small quantities of white portland cement and refractory, colored, and other types of cement not produced in Jamaica continued to be imported.

Expansion of the Rockfort plant was nearly completed during 1963 with this installation of a third rotary kiln which will double rated

Digitized by Google

capacity from 200,000 to 400,000 tons. The additional capacity should enable the company to meet the increased demand caused by a rising level of construction activity. The plant utilizes the wet process. Limestone is obtained from two nearby quarries on Long Mountain, clay from the bottom of Hunt's Bay west of Kingston, and gypsum from a local supplier.

Kaiser Bauxite Co. announced an agreement concluded with Bahama Cement Co. to supply low-grade bauxite for use in the cement to be made at a new plant at Freeport, Grand Bahama. Kaiser is to deliver between 70,000 and 250,000 tons of cement-grade bauxite over 10 years, and thus will help to compensate for a probable loss of part of Jamaica's cement export markets to Bahama's new plant.

Gypsum.—Large deposits of high-grade gypsum occurring in the eastern part of St. Andrew Parish constitute one of Jamaica's more important mineral resources. Total reserves of these deposits have been estimated as at least 84 million tons. Jamaica Gypsum, Ltd., a subsidiary of United States Gypsum Co., remained the only significant gypsum producer in 1963; the bulk of its output has been exported to the United States. The local cement industry has regularly consumed about half of the 14,000 tons of gypsum sold each year in the country, and most of the remainder has been used in the local manufacture of plaster for gypsum board and other building materials. Small quantities of alabaster have been cut into ornamental objects.

Jamaica Gypsum's quarries and crushing plant are just north of Bull Bay, and its pier and stockpiling facilities are at Harbour Head. The company has maintained a fairly uniform rate of production since the abnormally high levels of 1958 and 1959. Local sales also have been relatively constant, but exports were far below normal in 1961 and 1963, with the result that unusually large stocks have accumulated. Exports in 1963 totaled only 136,651 metric tons, and local sales decreased about 6 percent to 12,823 metric tons. Stocks at year-end amounted to 373,582 tons.

Limestone and Marble.—Limestone has been utilized extensively in Jamaica for road construction, fill and ballast material, aggregate for concrete and concrete blocks, and raw material for cement and lime. Thick limestone beds cover more than 60 percent of the island, so a virtually inexhaustible supply of this rock is readily available. Other hard rocks are relatively scarce and, for the most part, occur in the more inaccessible areas. Dolomite suitable for refractory and metallurgical purposes occurs on the island, but local demand for this stone has been insignificant. A wide variety of colored marbles suitable for facing stone and other ornamental purposes are found in St. Thomas Parish. Serge Island Jamaica Marble, Ltd., has recently started a quarrying, cutting, and polishing operation near Morant Bay and has begun to produce polished marble slabs for local use and for export. Banded travertine has been used locally as a building stone.

Except for the limestone equivalent of the cement produced, statistical data on production and consumption of limestone and marble are not reported regularly. The official estimate for total production by registered quarries in 1962 was 1,506,540 cubic yards, or approximately 1.7 million metric tons. The cement industry consumed

Digitized by Google

about 270,200 metric tons in 1962. Limekilns, notably those at Alcoa's Kirkvine alumina works and at Bamboo in St. Ann's Parish, probably consumed 100,000 metric tons or more. Most of the limestone output is used for roadbuilding.

Phosphates.—Much attention has been given to deposits of bat guano and associated phosphatic marl found in some of the numerous limestone caves on the island. This material has been collected and used by farmers as fertilizer, and some has been produced on a commercial scale and processed for sale as a dairy feed supplement and as fertilizer. Some caves worked have contained several thousand tons of phosphates, but most have yielded only a few hundred tons. Intensive prospecting probably would locate numerous caves with recoverable phosphates, but the relatively small average size of the deposits and the wide dispersion and difficult accessibility of the caves have discouraged any serious attempt to enlarge commercial recovery operations. Annual reported output in recent years has been less than a hundred tons of dried phosphates.

MINERAL FUELS

Petroleum.—As of 1963, all of Jamaica's requirements for mineral fuels and lubricants had to be imported, as the country has no known oil resources and only a few small uneconomic deposits of low-grade lignite. Oil exploration on the island by several companies has been unsuccessful thus far, and offshore drilling seems to offer the best remaining possibility of finding commercial quantities of oil. Jamaica Time Petroleum, Inc., still holds 23 oil prospecting licenses, but no field activity by the company has been reported for 1963. Fuel imports cost Jamaica an average of nearly US$20 million annually during 1959–63. This heavy outflow of foreign exchange will be reduced somewhat by the new 26,500-barrel-per-day Esso West Indies oil refinery and marine terminal at Kingston, which was completed in December. To go on stream early in 1964, this refinery will process imported crude oil into gasolines, kerosine, jet fuel, distillate and residual fuel oils, liquefied petroleum gas, and asphalt. The finished products will provide most of Jamaica's internal and bunkering requirements, with a surplus of about 30 percent for export to the Bahamas, Bermuda, and British Honduras. The new refinery's processing units include a crude oil pipestill; an asphalt vacuum pipestill; hydrofiners for naphtha, kerosine, and gas oils; a Powerformer catalytic reformer; and facilities for fractionating light ends. Esso also plans early installation of facilities for blending lubricating oils.

The Mineral Industry of the Netherlands Antilles

By Eugene R. Slatick [1]

PETROLEUM refining continued to be the most important industry in the Netherlands Antilles during 1963. It supported all other segments of the economy directly or indirectly and employed about 30 percent of a labor force of about 29,000. In both volume and value, petroleum was the most important trade commodity. Feedstock requirements for the two refineries (one on Aruba and one on Curaçao) continued to be met by imports, mostly from Venezuela.

Phosphate rock mining remained the second principal mineral industry, but its importance decreased. Of lesser importance were salt production from salt pans on Bonaire and Curaçao and limestone aggregate produced as a byproduct of phosphate operations. Sulfur was recovered as a byproduct of refining operations, but most of it was used by the refineries. Among the new mineral industries established in 1963, the most significant was the nitrogenous fertilizer complex on Aruba.

The Netherlands Antilles comprise two groups of three islands each, about 880 kilometers apart. The large group (Aruba, Curaçao, and Bonaire) covers an area of 921 square kilometers; the smaller group (St. Martin, St. Eustatius, and Saba), an area of 68 square kilometers. The principal cities are the capital, Willemstad on Aruba and Oranjestad on Curaçao. These are the sites of the two refineries on the islands. Together, the islands supported a population of 188,914 in 1960.

Since December 1954, the Netherlands Antilles have been fully autonomous in their internal affairs and constitutionally equal with the Netherlands and with Surinam. The sovereign of the Kingdom of the Netherlands is the titular head of government and is represented by a governor. The governor and his Council of Ministers form the internal government of the islands but are responsible to a unicameral legislature (Staten).

SOURCE MATERIAL

Data on production of refined petroleum products was obtained from Standard Oil Co. (New Jersey) reports and from the British Ministry

[1] Mineral specialist (petroleum), Division of International Activities.

Digitized by Google

of Power. Sulfur production was estimated from reported sulfur-plant capacities.[2] Other production data and all trade information were obtained from official statistics. Information on the new chemical complex was obtained from U.S. State Department Airgrams and commercial publication.[3] Data on additions to the Curaçao refinery came from Petroleum Management.[4] Information on other development was obtained mainly from U.S. State Department Airgrams and Dispatches.

PRODUCTION

Output of refined petroleum products in 1963 was about the same as in 1962. Limestone production was estimated to have decreased slightly and phosphate-rock production continued the downward trend that began in 1962. Production of marine salt was more than twice that of 1962. The increase was due to resumption of production on Curaçao, which accounted for about 38 percent of the total. Sulfur production was estimated to be same as in previous years.

TRADE

In 1962, as in the past, petroleum comprised the bulk of imports. There was a slight decline in crude-oil imports, the largest import item, but total petroleum imports rose by about 3 percent. Most of the increase was due to a rise in imports of residual fuel oil. Almost all petroleum-product imports, except specialty products not produced in the Netherlands Antilles, were either for additional refining or for reexport. Crude oil imports in 1962 were valued at Ant. f958.9 million,[5] compared with Ant. f184.7 million for refined products.

Nonmetal imports rose by about 45 percent in 1962 largely because of increased cement imports. Most of the 34 percent increase in metal imports was pipes and tubes. Nonmetal imports were valued at Ant. f1.4 million; metal imports, at Ant. f7.2 million.

Digitized by Google

In 1962, Venezuela supplied almost all the crude oil, most of the refined products, and almost half of the nonmetal imports. The Netherlands and the United States were the two largest suppliers of metals.

The volume of mineral exports rose by about 10 percent during 1962. Most of the increase was in petroleum product exports, which comprised about 99 percent of the total. The largest increase, almost 25 million barrels, was accounted for by residual fuel oil. Crude-oil reexports also increased. Metal exports, however, dropped about 26 percent, mostly because of a reduction in iron and steel scrap exports. Nonmetal exports were down about 12 percent largely because of a decline in phosphate exports.

Refined products continued to be the most valuable export item. They were valued at Ant. f1,262.1 million, compared with Ant. f12.3 million for crude-oil reexports, Ant. f6.8 million for nonmetals, and Ant. f1.3 million for metals.

As in the past, the United States remained the most important market for petroleum and phosphate exports. Italy was the largest market for metal exports.

COMMODITY REVIEW

NONMETALS

Cement.—No developments were reported in 1963 on the proposed construction of a cement plant on Aruba. The plant, which was proposed in 1962, was to cost Ant. f18.7 million, employ 100 persons, and produce 188,000 metric tons of cement annually. Most of the output was to be exported.

Digitized by Google

Limestone.—In 1963 limestone aggregate was produced mainly as a byproduct of phosphate mining on Curaçao. Some limestone aggregate was also produced on Bonaire. Most of the production was consumed by the local market. A small quantity, however, was reported to have been exported, principally to Surinam.

Nitrogeneous Fertilizers.—The four plants—ammonia, nitric acid, urea, and fertilizer—of the chemical complex at Barcadera, Aruba, began producing fertilizer materials and fertilizer during 1963. Production began at the Ant. f16.8 million ammonia plant in May 1963. It is operated by Antilles Chemical Co., a subsidiary of Standard Oil Co. (New Jersey). The plant, which is among the largest of its type in the world, has an annual production capacity of 110,000 tons. Base stock for the plant is refinery gas from the Aruba petroleum refinery. About two-thirds of the plant output will be used by the nitric acid and urea plants. The remainder will be shipped by special refrigerated tankers to other countries in Latin America.

The other plants of the complex went into operation in November 1963. They are operated by Aruba Chemical Industries, which is jointly owned by Standard Oil Co. (New Jersey) and International Development & Investment Co. (C. & I. Girdler Investment, Ltd., and Phoenix Overseas, Ltd.). The Ant. f2.4 million nitric acid plant has an annual production capacity of 50,000 tons, the Ant. f9.3 million urea plant an annual capacity of 75,000 tons; and the Ant. f3.7 million fertilizer plant, an annual capacity of 132,000 tons. The entire output of nitric acid will be used by the fertilizer plant. Most of the urea and fertilizers produced will be exported to other countries in Latin America. New export markets are expected to be opened when the Netherlands Antilles candidacy for associate membership in the European Economic Community (commonly referred to as the Common Market) receives final approval.

Phosphate Rock.—Phosphate rock remained the only important mineral produced in the Netherlands Antilles. Deposits of this mineral occur on both Curaçao and Aruba, but only those on Curaçao were being mined. Almost all the phosphate rock produced was exported to the United States, where its low fluorine content commanded a premium price.

During 1963 the Curaçao Mining Co. continued to be the sole producer of phosphate rock. Although mechanization has been useful in working lower grades of ore, small pockets of highly concentrated ore must be sorted by hand. Employment at the mine dropped to 480, compared with 524 in 1962 and 633 in 1961.

The Aruba Exploration & Mining Co., which was founded in 1960, had not begun production from deposits on the southeastern end of Aruba. The deposits, which are of too low a grade to be exported, are expected to be used to make phosphoric acid for the new fertilizer industry.

Pumice.—The Antillian Aggregate Corp. retained the option to mine pumice deposits on St. Eustatius, but operations continued to be delayed by lack of capital to build facilities needed to take the ore off the island. The pumice deposits, estimated at 400 to 500 million tons, outcrop in the cliffs along the southwest coast of the island.

Digitized by Google

Salt, Marine.—Salt production continued to be mainly from salt pans on Bonaire, although salt was also produced on Curaçao. A Panamanian subsidiary of the International Salt Co. investigated the feasibility of constructing salt pans in a 3,500-hectare area on Bonaire. Annual production of this installation would be about 450,000 tons.

Sulfur, Recovered.—In 1963 sulfur recovered from petroleum refining was estimated to be the same as in previous years. Most of it was used in manufacturing sulfuric acid for refining purposes.

MINERAL FUELS

During 1963, petroleum refineries, which ranked among the largest in the world, continued to be the mainstay of the Antillian economy. Employment at the refineries, however, continued to drop because of continued automation of refinery operations. Employment was 8,712, compared with 9,657 in 1962 and 10,515 in 1961.

In 1963, as in previous years, oil processing installations were modernized or replaced by new units. An 85,000 barrel-per-day thermal cracking unit and a 20,000 barrel-per-day thermal reforming unit were added to the Curaçao refinery in 1963. No information was available for improvements at the Aruba refinery. The Curaçao refinery was operated by Shell Curaçao, N.V., a member of the Royal Dutch/Shell Group. The Aruba refinery was operated by Lago Oil & Transport Co., Ltd., a subsidiary of Standard Oil Co. (New Jersey).

Throughput increased slightly during 1963 and was about 29 percent more than designed capacity. Crude oil throughput decreased by about 1 percent, but throughput of partially refined oils rose by about 10 percent. As in the past, total throughput greatly exceeded the combined designed distillation capacity (Aruba refinery, 440,000 barrels per day; Curaçao refinery, 210,000 barrels per day). During 1963 there was a continuation of the informal agreement between the refining companies and Venezuela to limit crude oil throughput so that more Venezuelan crude oil could be refined domestically. This limitation, however, was partly offset by the trend to run more partially refined oil. Throughput has been as follows:

Type of feed stock:

	Quantity (thousand barrels)				
	1959	1960	1961	1962	1963
Crude oil	257,603	259,608	267,474	271,234	268,820
Partially refined oils	14,407	19,645	31,801	34,596	37,960
Total	272,010	279,253	299,275	305,830	306,780

In 1963, the Netherlands Antilles candidacy for associate membership in the European Economic Community was still being discussed. There was no change in the agreement to limit the duty-free entry of Antillian petroleum products to the Common Market to 17 million barrels a year. Nor was there any change in the right of the European Commission to suspend entry of Antillian products into the Common Market if the market was in serious difficulties. Member countries also continued to have the right to temporarily suspend imports into their territories if their full quotas would have adverse effects. All these arrangements, however, were subject to review because the future common tariff for petroleum products still remained to be fixed and a number of related problems had to be settled.

The Mineral Industry of Trinidad and Tobago

By Gordon W. Koelling [1]

THE PETROLEUM industry continued to occupy a dominant position in the economy of Trinidad and Tobago during 1963 and was the source of 40 percent of ordinary government revenue. It also accounted for approximately 12 percent of the 119,790 workers employed at the end of the year in nonagricultural undertakings (but including sugar estates) employing 10 or more. Crude oil production accounted for only 3 percent of that from all of Latin America, but refinery output was about 10 percent of total for the same area. Imports provided approximately 60 percent of the feedstock for the two Trinidad and Tobago refineries, one of which was among the world's 10 largest. Production of other minerals was limited principally to construction materials (including natural asphalt and pitch sand), although the output of nitrogenous fertilizers was also significant. Small quantities of sulfur recovered as a byproduct of refinery operations were consumed at the refineries.

The mineral industry of Trinidad and Tobago accounted for approximately one-third of the total 1963 gross national product of around BWI$1,000 million.[2] Of this total, Trinidad was responsible for the greatest amount. The contribution of Tobago could be regarded as inconsequential. Exports and reexports of minerals during the same year comprised approximately 77 percent of the country total, valued at BWI$638 million. An estimated 62 percent of total imports, valued at BWI$641 million, was metals and minerals.

Trinidad and Tobago became an independent state of the British Commonwealth, having its own constitution and bicameral legislature, on August 31, 1962. Geologically, the islands, which together have an area of 5,128 square kilometers (Trinidad, 4,828 square kilometers; Tobago, 300 square kilometers), are an extension of the Venezuelan portion of the South American continent. Together the islands supported a population of 827,957 in 1961.

No significant mining or petroleum legislation was enacted during 1963 and Government policy was unchanged in favoring development of petroleum and other mineral industries by private enterprise. The country's second 5-year development plan (1964–68) was approved during the latter part of 1963. This plan, although acknowledging that the petroleum industry will continue to form the basis of economic

[1] Geographer, Division of International Activities.
[2] One British West Indies dollar (BWI$) equals US$0.59.

Digitized by Google

viability and political stability, has as its major goal the expansion of agriculture and manufacturing.

SOURCE MATERIAL

Most production and trade statistics were obtained from publications of the Central Statistical Office of Trinidad and Tobago. Some statistical information was also obtained from official U.S. sources. Considerable data on recent developments was provided by various issues of Petroleo Interamericano and Petroleum Press Service.

PRODUCTION

Crude oil production, which had been increasing steadily, declined slightly during 1963. However, output of refinery products processed from imported and indigenous crudes increased 13 percent. Production of limestone and sand and gravel rose 12 and 24 percent, respectively, but output of clay, which dropped 20 percent from 1962, continued its downward trend. No other production changes of major significance occurred during the year.

TRADE

Exports of crude oil, refined petroleum, and natural asphalt had a combined value of BWI$492 million in 1963. The value of metals and nonmetals exports was about BWI$5 million. Shipments of metals and minerals were generally destined for the United States, countries of Western Europe, and nearby areas in Latin America, with no significant break in the customary trade pattern.

Trinidad and Tobago 1963 petroleum imports were valued at BWI$301 million and consisted almost entirely of crude oil destined for processing locally. During 1962, the latest year for which a breakdown for imports of metals and minerals was available, receipts of these items were valued at BWI$370 million. Metals accounted for 8 percent of this total; nonmetals, 1 percent; coal, coke, and lignite, 15 percent; and petroleum, 76 percent.

COMMODITY REVIEW

METALS

All requirements for metals were met by imports. The small iron ore deposits located in northern Trinidad were not being exploited. Bauxite, mined in Surinam, was brought to Trinidad in shallow draft vessels for transshipment to large freighters, without entry in the customs records.

NONMETALS

Most nonmetals requirements were supplied wholly or in large part from local production. Major exceptions were sulfur, salt, and barite.

The largest single-line ammonia plant in the world was completed at Point Lisas in late 1963. This 235,000-ton-per-year plant is an extension of a smaller plant built in 1960 and is owned by Federation Chemicals, Ltd., a subsidiary of W. R. Grace and Co. of New York. Included in this expansion program was the construction of facilities for the shipment of liquefied ammonia in specially designed, low-temperature tankers. Previously, ammonia from Point Lisas was used primarily for domestic production of solid-state nitrogenous fertilizers.

MINERAL FUELS

Petroleum.—The number of wells drilled declined for the third successive year in 1963. Of 234 wells drilled during the year, 203 were producers. This was a lower success ratio than in the preceding year when 255 wells out of a total 280 drilled were productive. Total footage drilled also declined from 1,506,000 in 1962 to 1,246,000 in 1963. An 8-week strike against BP (Trinidad), Ltd., during 1963 was probably responsible in part for the decrease in drilling activity.

Two new offshore discoveries were made by Dominion Oil, Ltd., (subsidiary of Standard Oil Co. of California) during 1963. One of these wells is located in the Gulf of Paria 12.5 miles west of Couva, the other is east of Point Galeote. At yearend, testing and further drilling were underway to determine the significance of these discoveries. Total proved crude reserves in Trinidad and Tobago were reported at 500 billion barrels as of mid-1963.

Despite declining productivity of most onshore fields and the strike against BP, output of crude petroleum was only 0.45 percent less than

Digitized by Google

in 1962. Decreases in onshore production were largely offset by a rise in output from the Soldado offshore field. This field, owned by Trinmer, Ltd., (Texaco, Shell, and BP), accounted for 27 percent of total production during 1963. The share of output accounted for by other companies, which produced from a total of 16 fields, was as follows: Texaco Trinidad, Inc., 39 percent; BP (Trinidad), Ltd., 20 percent; Shell Trinidad, Ltd., 11 percent; Trinidad Canadian Oils, Ltd., 2 percent; Premier Consolidated Oil Fields, 1 percent; and Dominion Oil, Ltd., less than 0.5 percent. Crude oil gravities varied considerably with those of most crudes produced ranging from 15° to 35° API.

Early in 1963, Trinmer announced initiation of a major development program in the Soldado field—involving additional development drilling, expansion of the gathering system, and installation of gas injection facilities. Plans also called for drilling seven stepout wells.

The country's two refineries, the 275,000-barrel-per-day Texaco plant at Pointe-a-Pierre and the 62,00-barrel-per-day Shell plant at Point Fortin, had a combined average throughput of 327,900 barrels per day in 1963. This was nearly 10 percent greater than the average throughput during 1962. Most of the Texaco refinery's crude feedstock was imported, primarily from Venezuela and the Middle East. The Shell refinery processed indigenous crude only.

During 1963, a cyclohexane unit with an annual capacity of approximately 240,000 barrels was placed on stream at the Texaco refinery. This unit produces benzene, toluene, and extra pure cyclohexane. Production of the latter is by a process involving the catalytic hydrogenation of benzene.

Nearing completion at the same refinery at yearend was a 2,700-barrel-per-day lubricating oil plant. Major units in this plant will include vacuum distillation and furfural solvent facilities. When placed on stream, this will be Texaco's largest foreign lubricating oil installation.

Work was also in progress to expand secondary processing facilities at the Shell refinery. Here, a 6,700-barrel-per-day platformer was placed on stream during 1963 and an 18,000-barrel-per-day hydrotreater was under construction at the end of the year.

Natural Gas.—The output of natural gas, almost all dissolved in or associated with crude oil, has declined recently; in 1963 it was 7 percent lower than in the peak year of 1961. Proved reserves as of December 1963 were reported at 1 trillion cubic feet. Two new gas pipelines were under construction at yearend. One of these, a 16-inch diameter, 42-mile line, was being constructed by Shell to link the Penal-Barrackpore field with Port-of-Spain. The other, a 17-mile line, was being built by Texaco between the Forest Reserve field and its refinery at Pointe-a-Pierre. This 16-mile pipeline will replace an existing 12-inch line that will be converted to transport crude oil.

Natural Asphalt and Pitch Sand.—Natural asphalt is cut from the surface of Trinidad's large asphalt lake, and pitch sand is dug from the shores of this same lake. There were no major developments during the year under review with respect to these commodities.

The Mineral Industry of Argentina

By Sumner M. Anderson [1]

ALTHOUGH scattered signs of increased activity in the mining industry accompanied an incipient improvement in the overall economic situation during the latter months of 1963, production levels for the year as a whole responded to the general 1962–63 business recession with a 4.2 percent decline. The petroleum industry, active since 1907, did not become a dynamic force in the economy until exploration and drilling contracts were concluded with private companies in 1958 and 1959; on November 15, 1963, having virtually achieved self-sufficiency in petroleum in the preceding year, those contracts were unilaterally annulled. In the field of metallics, the only approach to internal sufficiency—aside from the iron and steel industry that has depended heavily on the importing of basic raw materials—has been in mining, smelting, and refining lead and zinc; although iron ore, silver, beryllium, tantalite, and tungsten have been mine production items of economic significance. Reserves of lead, zinc, silver, bismuth, vanadium, and low-grade and metallurgically difficult iron ore—as well as those of beryllium, tantalite, and tungsten which are produced primarily for export—appear to be fairly abundant. The exploration of deposits of copper, cobalt, tin, lithium, gold, manganese, and uranium has been undertaken on a relatively small scale, and little precise information is available on the extent of reserves. Argentina is dependent on foreign sources for part of its required iron and steel and, except for lead and zinc, most of its nonferrous metals. Nonmetallics and solid fuels present an exceptionally varied array of production items among which cement had the second largest 1963 output in South America. Borates, bentonite, common clay, diatomite, fluorite, granite, lime, limestone, obsidian, onyx, rhodochrosite, salt, and spodumene ordinarily are produced for export either exclusively or in excess of domestic consumption requirements. Barite, cement, chalk, gypsum, marble, and mica are both exported and imported. Argentina depends entirely or partly on imports for coal and coke, certain special types of clay, mineral abrasives, graphite, magnesite, mineral fertilizers, sulfur, talc, and minerals for construction, the last group being chiefly attributable to convenience of river transport from Uruguay.

Despite this diversity of activity, Argentinian mineral importance internationally in 1963 was confined to production of 13 percent of the world output of beryl and only about 1 percent each of its lead,

[1] Chief Latin America Specialist, Division of International Activities.

Digitized by Google

zinc, and crude petroleum. Domestically, the total value of mine production in 1963 has been estimated at slightly more than 1 percent of the gross national product of 1,395 billion Argentine pesos. (The monetary exchange rate has been unstable; the average for 1963 was 139.2 Argentine pesos for US$1.00.) Adding the petroleum, iron and steel, and cement industries would probably more than double the percentage figure, which would still be low for the second largest country in South America, facing a need for industrial expansion. Deterrants to mineral development have included (1) resources that are poor in quality, small in size, isolated from transportation facilities in mountainous areas, or inadequately explored; (2) lack of skilled labor and technicians; (3) shortage of investment capital; (4) mining laws devoid of provisions for depletion allowances and of a time limit for development of a property; and (5) a nationalist policy discouraging to foreign investment capital.

To overcome the first of these deterrents, perhaps the most significant development of 1963 was a US$3 million program of aerial mapping and geological studies initiated with the cooperation of the United Nations to survey the western Provinces of Mendoza, Neuquén, and some areas of San Juan. The studies will take 3 years and may reveal previously unknown or unrecognized resources. The Dirección Nacional de Economía Minera was planning a similar program in the Provinces of Salta, Jujuy, Tucamán Catamarca, and La Rioja scheduled to begin in July 1964. The Departamento Minería of San Juan began reconnaissance and geological surveys in regions of that Province, and similar surveys elsewhere were scheduled by the Dirección Nacional de Geología y Minería.

More than 75 percent of the population is urban; about one-fourth live in greater Buenos Aires, and seven other cities have 100,000 or more inhabitants. Distribution of the labor force shows 26 percent engaged in industry, 19 percent in agriculture, 12 percent in transport and communications, and less than one-half percent in mining. The recent attention to mineral exploration is recognition of the imbalance between industry and the production of mineral raw materials to feed it.

SOURCE MATERIAL

Material was obtained from annual reviews of the minerals, iron and steel, and petroleum segments of the industry by the U.S. Embassy, Buenos Aires, and from a preliminary manuscript chapter on the mineral industries from a forthcoming book on Argentina by Merwin L. Bohan, consulting economist and ex-United States Ambassador to the Organization of American States. Contributions from published sources included:

Engineering and Mining Journal, Progress in Latin America, April 1964, pp. 115–116, McGraw Hill Publishing Co., New York.

Stoll, W. C., Metallogenic belts, centers, and epochs in Argentina and Chile, Econ. Geol., v. 59, 1964, pp. 126–135.

Mining Journal (London), Mining Annual Review 1964, June 1964, p. 231.

Direccion Nacional de Economia Minera, Buenos Aires, Boletin Informativo, Año III, No. 36, Deciembre 1962.

Direccion Nacional de Energia y Combustibles, Combustibles, 1962, Buenos Aires.

PRODUCTION

Production statistics are compiled by the Dirección Nacional de Economía Mineral (National Office of Mineral Economics); they are published in part in their monthly Boletin Informativo and are supplied in greater detail through the U.S. Embassy in Buenos Aires. They are based primarily on mine and plant shipments, although for a few items they have been rejected in favor of export figures. Details of the iron and steel, cement, and petroleum industries have been supplied, also through the U.S. Embassy, by the Centro Industriales Siderúrgica, the Camara Laminadores Industriales Metalúrgicos Argentina, the Asociación de Fabricantes de Cemento Portland, the State oil agency (YPF), and private companies.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Antimony	4				
Beryl, 11 percent BeO[1]	3,026	1,050	1,350	1,325	907

[1] Exports.
[2] Estimate.
[3] United States imports from Argentina.
[4] Final figure; supersedes that given in commodity chapter, volume 1 and/or 2.
[5] Data not available.
[6] Included under Columbite-tantalite.
[7] As reported by Direccion Nacional de Economia Minera—appears to be incomplete.

TRADE

Comercio Exterior, volumes 1 and 2 for both 1961 and 1962, as published by the Argentine National Bureau of Statistics and Census, is the official source of the mineral export and import tables, with the few exceptions noted. The same government agency supplied the preliminary figures for 1963 cited in the commodity review section. Export values are f.o.b.; import values are reported as including cost and freight (C. y F.) without mention of insurance, which presumably is excluded.

The initial par value of the Argentine peso was established on January 9, 1957, as 18 pesos per U.S. dollar. However, since January 1959 no market transactions based on the par value have taken place but have been conducted without restrictions in a free-exchange market. Exchange rates, as measured by those in effect at the end of quarter year, have fluctuated as follows, in terms of pesos per U.S. dollar:

Year:	*High*	*Low*	*Yearend*
1961	M$N83. 04	M$N 82. 71	M$N83. 02
1962	135. 00	82. 95	134. 10
1963	149. 80	132. 50	132. 50

Digitized by Google

In 1962 the values of Argentine exports and imports of minerals and mineral products, exclusive of advanced manufactures, represented approximately 0.2 and 2.7 percent, respectively, of a gross national product that was estimated at M$N1,115 billion.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962		
	Quantity	Quantity	Principal destinations	Value, f.o.b. (thousand pesos)
Metals:				
Aluminum ingots, bars, plates, sheets, and other forms.	1,143	12	Mainly to Uruguay	1,576
Beryl	1,350	905	United States 855; Japan 50	32,151
Columbite.....kilograms	921			
Copper and copper alloys:				
Copper concentrates	1,615	1,708	Mainly to Japan	21,109
Copper-silver concentrate	166	2	All to Belgium	882
Copper matte	212	209	Japan 195; United Kingdom 14	4,578
Copper ingots, bars, plates, sheets, and other forms.	3	12	Mainly to Uruguay	1,643

COMMODITY REVIEW

METALS

Aluminum.—In 1961 the Argentine Government authorized the Kaiser Aluminum and Chemical Corp. to build a 22,000-ton aluminum plant at Puerto Madryn in the Patagonian Territory of Chubut. Kaiser immediately formed the Argentine company Fabrica Argentina de Alumina, S.A., for that purpose. The plant had not been completed by the end of 1963.

In 1961 Industrias Siderurgicas Grassi, S.A., announced plans to build alumina and aluminum plants in southern Mendoza Province; the aluminum plant was to have a capacity of 10,000 tons a year. In 1962 Reynolds International, Inc., was authorized to build a 22,700-ton aluminum plant near either Puerto Madryn or Comodoro Rivadavia, which is also in the Territory of Chubut.

Argentina has no bauxite deposits of its own. Final utilization of bauxite imports listed for 1961 and 1962, plus 4,292 tons imported in 1963, has not been reported.

Beryl.—Argentina in 1963 was third largest producer of beryl in the world, following Brazil and the U.S.S.R. Since the Argentine Government freed producers in 1961 from exclusive sale to COCOMINE (Comité de Comercialización de Minerales), the Government mineral

Digitized by Google

sales committee output has depended largely on the international price factor. It was not adversely affected until September 1962, when prices on ore imported into the United States, the predominant market, began to decline. Argentine production declined in 1963, but toward the end of the year some producers who had shut down reinitiated operations. Production of high-quality mineral, containing as much as 10, 12, and more percent BeO, has been from an extensive pegmatite zone in the Pampean Ranges—mined primarily in the Provinces of Catamarca, La Rioja, Córdoba, San Luis, and occasionally San Juan. Some beryl-bearing pegmatites are situated farther south in Rio Negro.

All Argentine-produced beryl has been sold abroad except an estimated 24 tons consumed annually by Cía. Argentina Berilo y Aleaciones which, when last reported in 1960, was producing beryllium-copper alloy, beryllium oxide, and beryllium hydroxide for unrecorded disposal.

Columbite and Tantalite.—The ore minerals are coproducts of beryl from mining pegmatites. They have found a steady market abroad, principally in the United States.

Copper.—Since 1851 Argentina has been a persistent but an ineffective producer of copper, despite its proximity to the great Chilean copper belt. Peak production was attained in 1908 with about 2,500 tons of copper in ores and concentrates. The average through 1950 was between 250 and 350 tons, and the peak since then was about 750 tons produced in 1957. Production from small rich veins in generally remote areas of the high Andes has been an insignificant fraction of the approximate 30,000-ton annual industrial requirement of the country, which customarily is supplied by imports from Rhodesia, the United States, and Chile.

Iron Ore.—Domestic resources of iron ore are inadequate for the expanding steel industry. Production in 1963 dropped 22 percent from that of 1962 and was 41 percent below that of 1960. Nearly all of the ore production has been from the Zapla deposit in the Province of Jujuy, which feeds the state-owned charcoal furnaces of the Establecimiento Alto Hornos de Zapla. The ore contains only 35 to 45 percent iron and is high in phosphorus and silica. The proved reserve is 110 million tons; possible reserves have been estimated to total 400 million tons.

In the Province of Rio Negro, about 19 kilometers from the Atlantic Coast, the undeveloped Sierra Grande deposit has 48.5 million tons of measured ore, containing an average of about 55 percent iron but also a high phosphorus content. Unmeasured reserves may be an additional 200 million tons. A survey of the deposit by the international consortium MISIPA (Minera y Siderúrgica Patagónia—Sierra Grande, S.A.) continued in 1963 and was expected to extend for 3 more years to embrace detailed studies of mine and smelter production methods, market outlets, transportation and power supplies, and other facets of industrial integration. Early in 1961 the Argentine Government approved a US$150 million contract with MISIPA to develop the deposit. Studies underway at yearend were being financed by a 1963 technical assistance loan of US$400,000 from the Inter-American Development Bank plus US$250,000 provided by MISIPA.

Digitized by Google

The project can become a major operation, but it will be some time before commercial mining will begin, assuming the fruition of forecasts. Plans call for initial shipment of ore to the San Nicolás steel plant of SOMISA where, because of the high phosphorus content, it can be used to make up only 10 percent of the blast-furnace charge. Later MISIPA expects, if the ore reserve is adequate, to establish an industrial complex at a site yet to be determined but probably at Pureto Madryn to draw power from the projected Chocan hydroelectric installation and utilize coal from Rio Turbio. The planned complex includes plants with annual capacities to produce 1 million metric tons of iron pellets suitable for blast furnace charge, 330,000 tons of sponge iron, and 296,000 tons of steel.

Less important deposits of iron ore have been found in the provinces of Mendoza, Salta, Cordoba, and Buenos Aires; some may have been exploited on a very small scale locally.

The metallic raw material needs of the iron and steel plants, beyond the iron ore contribution of the Zapla mine and some suspected domestic production of ferromanganese, have been supplied by imports of iron ore from Peru, Brazil, and Chile; pig iron from the U.S.S.R., West Germany and Brazil; billets, blooms, and slabs chiefly from West Germany, Belgium, and Sweden; and ferromanganese from Belguim, France, and the United States.

Iron and Steel.—The business recession that began early in 1962 and continued into 1963 struck the Argentine metals industry with particular force. Output of finished steel products was considerably less than capacity and 16 percent less than the 1961 production record. In contrast, and as a process of import substitution, major increases were made in the production of pig iron, crude steel, and semifinished steel. Producers sought and obtained export outlets for their manufactures amounting to 117,000 tons, a record high. Steel is not a traditional export product, and overseas sales were expected to diminish sharply in 1964. Argentine apparent consumption of finished steel in 1963 has been calculated as 1,460,900 metric tons, but reduction of stocks already in the country may have made actual consumption 100,000 to 200,000 tons higher. Iron and steel producing capacities at the end of 1963 were:

Plant:	*Capacity, metric tons per year*			
Government owned:	*Pig iron*	*Crude steel*	*Semifinished steel*	*Finished steel*
SOMISA [1]	630, 000	900, 000	800, 000	1, 000, 000
Zapla [2]	160, 000	150, 000	135, 000	120, 000
Private [3]	10, 000	500, 000	350, 000	1, 400, 000
Total	800, 000	1, 550, 000	1, 285, 000	2, 520, 000

[1] Sociedad Mixta Siderúrgica Argentina plant at San Nicolas, Buenos Aires Province, produced 385,500 tons of pig iron and 510,700 tons of crude steel in 1963; it was the sole producer of slabs.
[2] Establecimiento Altos Hornos de Zapla, a property of Fabricaciones Militares at Zapla, Province of Jujuy, produced 37,200 tons of pig iron in 1963.
[3] Altos Hornos Guemes, which started in 1963 in Santa Fe Province, and other plants and foundries including Acindar, Dalmine, Gurmendi, Santa Rosa, Siderca, A.B.K. Electrometalúrgica, La Cantábrica, and San Martin.

Capacities of SOMISA for pig iron and crude steel are out of balance. Long-range plans include addition of at least one more blast

Digitized by Google

furnace, a basic oxygen steel furnace and oxygen plant, additional blooming facilities, and more equipment for the finished steel lines to complete an integrated mill with 2 million tons of crude steel capacity. Expansion progress in 1963 included installation of a fifth open-hearth furnace, a cold sheet line, a hot sheet mill, and a tinplate line.

Zapla confined itself to small-scale pig iron production until the late 1962 completion of an integrated steel plant consisting of two new blast furnaces, three Thomas converters, and a rolling mill for structural shapes. The plant was expected to serve the regional market of northwestern Argentina, but the new facilities were not put to work in 1963, except part use of one of the blast furnaces.

Acindar, Industria Argentina de Aceros, S.A., operating in the Province of Santa Fe, is the largest of the private steel companies. It completed in 1963 the installation of a merchant Morgan rolling mill in its Villa Constitución plant, raising its finished steel capacity to about 420,000 tons. At the same time, crude steel capacity of its Rosario plant was increased 25,000 tons to 95,000 tons. The company possesses no facilities for producing pig iron, but plans for an integrated plant call for an eventual blast furnace capacity of 500,000 tons, an open hearth capacity of 650,000 tons, and a 100,000-ton expansion of semifinished steel output.

Gurmendi was adding 180,000 tons of finished steel capacity to its previous 60,000 tons and planning installation of crude steelmaking facilities and later blast furnaces for pig iron.

The expansion program of Establicimientos Metalurgicos Santa Rosa, S.A., scheduled for completion in 1964, involved installation of a 25-ton electric furnace at its Tablad plant in Buenos Aires Province to raise crude-steel capacity from 60,000 to 90,000 tons, and amplification of its finished steel lines to raise capacity from 90,000 to 130,000 tons.

Propulsora Siderúrgica, not yet in production, was engaged in a big project for construction of a plant near La Plata, Buenos Aires Province, capable of producing annually 1.4 million tons of pig iron, 1.3 million tons of crude steel, and 1.1 million tons of semifinished steel, at an estimated cost of slightly more than US$200 million. The Italian-capital Techint company, that controls Siderca and Dalmine, was sponsoring the project but facing a problem of financing.

Other projects were underway or being planned during 1963. Some were comparatively small and others, including a few of major proportions, showed uncertain prospects of fulfillment.

Lead and Zinc.—Mine output of lead and zinc, the two most important indigenous metals produced in Argentina, accompanied the general business recession of 1962–63 with declines of 9.9 and 8.7 percent, respectively. Lead production from mines and smelters was adequate or nearly so to meet the needs of the country, but there was not enough surplus to permit sales abroad until 1963, when 270 tons of lead concentrates were exported. Production costs are high, and the industry requires and receives tariff protection of 150 percent surcharge on lead-ingot imports. The price of lead produced and sold in Argentina has been roughly double the world price and has created considerable consumer demand for reduction of the surcharge on imports.

Digitized by Google

Production of zinc is determined by that of lead, with which it is associated in the ores. In recent years, the ratio of zinc to lead in ore mined has increased. National consumption since 1960 has been satisfied by the domestic-smelting capacity without need for imports of slab zinc. Part of a regular and inevitable oversupply of zinc concentrate found export markets principally in Europe, but appreciable tonnages have contributed to an ever-growing accumulation of stocks that probably exceeded 140,000 tons at the end of 1962. Stocks were reduced a little in 1963 when increased world demand and prices provided an export outlet for 47,372 tons of concentrate and 3,179 tons of slab zinc, compared with 19,682 tons of concentrate and no refined metal exported in 1962.

Cía. Minera Aguilar, a subsidiary of the St. Joseph Lead Co., was the only major producer of lead-zinc ores and concentrates in Argentina. In its 28 years of mining and milling, from early 1936 through 1963, it produced 644,926 tons of exceptionally high-grade lead concentrates and 983,503 tons of zinc concentrates from its Aguilar group of mines situated about 4,420 meters above sea level in the Department of Humahuaca, Province of Jujuy, in the extreme northwestern part of the country. With outstanding application of operational efficiency, the company in 1963 succeeded in holding production costs to a slight increase, despite increases of 21.4 percent in basic wages and 50 percent in cost of supplies. The lead concentrates are smelted by several Argentine smelters and fabricators. The zinc concentrates, other than those exported and stocked, move by rail to Borghi, a port on the Parana River north of Rosario, for treatment by Sulfacid, S.A., which is owned jointly by Aguilar and Bunge & Born, international dealers in agricultural products. Sulfacid facilities include roasters, a sintering plant, an acid plant, and—since late 1962—a modern electrolytic zinc plant with a capacity of 6,000 tons per year of Special High-Grade zinc, that produced only about 4,000 tons in 1963. Sulfacid sinter is shipped to the sintering and electrothermic zinc smelting plant of Cía. Metalurgica Austral-Argentine S.A.C.I.G. (43.3 percent owned by Aguilar) at Comodoro Rivadavia in Patagonia, which has a capacity to produce 12,000 tons of prime western zinc per year.

Cía. Minera Castaño Viejo, a subsidiary of the National Lead Co., was the second largest lead-zinc producer from its Castaño Viejo mine in San Juan Province near the Chilean border, but gradual depletion of ore reserves of that mine contributed to the decline of total lead-zinc production for Argentina in 1963, and the company embarked on an extensive exploration program. Castaño Viejo lead concentrates, and most of those from Aguilar, have been treated at Puerto Villelas plant of the National Lead Co. at Barrangueras, Chaco Province.

Small lead-zinc mines and smelters productive in 1963 have not been identified. Those active in the recent past include the following:

Manganese.—Deposits of manganese ore are small, scattered, and of too low grade (ranging from 15 to 40 percent contained metal) to be competitive in the world market. Production, mainly from the Provinces of Santiago de Estero and Cordoba, has been protected by a 100-percent tariff on imports. No imports have appeared in the officially released statistics, but the recent decline in the production of 30 to 40 percent grades has been attributed to imports of high-grade Brazilian ore under reduced charges granted to LAFTA (Latin American Free Trade Area) member countries. The ore is consumed largely by the steel industry as an additive either to pig iron furnaces or directly to the steel in open-hearth furnaces, although a plant reportedly inaugurated in 1957 in Mendoza may be supplying part of the open-hearth feed in the form of ferromanganese. Minor quantities of ore are used in the glass and chemical industries and for electrodes.

The Farellon Negro manganese deposit in the Agua de Dionisio district of Catamarca Province has been under investigation since 1958 by the Government-created YMAD (Yacimientos Mineros de Agua de Dionisio). The deposit reportedly contains 200,000 tons of very low-grade (9 to 20 percent manganese) ore with 10 to 12 troy ounces of gold and 200 ounces of silver per ton which, if true, should warrant its development as a precious metal mine. The validity of the precious metals content is questionable, and tentative plans are for initiation of a manganese-ore-production operation in 1966.

Digitized by Google

Precious Metals.—Since known depletion of ore in the vein mines of Cía. Minera Los Marayes in San Juan Province and Empresa Minera del Huaracó in Neuguén Province appears to have forced their closure towards the end of 1961, gold production has been limited to that contained as a byproduct in the ores of other metals and possibly recovered from small placer operations. (See manganese.)

The only metallic silver presently refined in Argentina is recovered in the process of smelting lead, and virtually all of it can be traced to the lead ores mined by Cía. Minera Aguilar in the Province of Jujuy.

Tin.—Internationally, Argentine production of tin is insignificant. The economically exploitable tin-silver vein and placer ores in the high mountains at Pirquitas, Province of Jujuy, were reported to be exhausted and the mines and mills closed in late 1958, leaving unexplained the origin of the continued small but steady production and exports of tin and tin-silver concentrates.

The only tin smelter to operate in Argentina since the close of World War II was closed in 1957, dismantled, and scrapped.

Tungsten.—During World War II tungsten was the most valuable mineral product in Argentina; average annual output in the years 1939–45 was 1,580 tons of concentrates of 60 percent WO_3 equivalent. Production fell nearly to the vanishing point in 1950 and then slowly rose to 600 tons by 1953; the annual average for that 7-year period was only 250 tons. In mid-1954 a 5-year, fixed-price purchase contract with the U.S. Government boosted the 1954–58 annual average to 1,079 tons. Thereafter through 1961 COCOMINE (Comité de Comercialización de Minerales), the Government mineral sales committee, became the mandatory sole purchaser of tungsten ore and supported mining activity at a reduced level, averaging 790 tons a year, by paying a subsidy price of M$N180 per kilogram for ore that was then sold to export markets for M$N50 to M$N60 per kilogram. At the end of 1961 legislation freeing tungsten and beryllium from Government control came into effect, permitting producers to sell their ore either in the open market or to COCOMINE, but early in 1963 COCOMINE—having depleted its funds—announced that as of April it would no longer purchase tungsten ore. When April arrived, all important tungsten mines had been shut down, and continued operation by small mines only on an irregular basis accounted for the 144 tons produced in 1963, a 75 percent reduction in output from the 576 tons in 1962. Recovery will have to await substantial improvement in international demand and prices.

Various mines in San Luis Province, most important of which was the Los Condores mine and mill of SOMISA (Sociedad Minera Argentina, S.A.), have yielded more than half of the country's past production of both wolframite and scheelite. Second largest producing area was the Province of Córdoba, having 29 known deposits. Occurrences that have been worked from time to time are widely scattered in at least six other provinces: Rio Negro, La Rioja, San Juan, Catamarca, Jujuy, and Mendoza. Except for Rio Negro and Jujuy, all these provinces encompass the Pampean Range where tungsten minerals occur as disseminations in granite, in tungsten-bearing pegmatites and aplites, as wolframite or scheelite or both in quartz veins, and as replacement deposits of scheelite in crystalline limestone

Digitized by Google

and granulite. All of the bismuth produced in years past was by-product of these ores.

Uranium.—Argentina does not have a known resource potential for more than modest production of uranium. Under a special appendix of 1956 to the Mining Code, all radioactive minerals are owned by the Argentine Government, and authority for their exploration and exploitation rests with the Comisión de Energia Atomica acting in cooperation with the individual provincial governments. Deposits have been found in the Provinces of Mendoza, La Rioja, Chubut, and possibly elsewhere, and plants for ore treatment and production of yellow cake concentrates have been erected. Sales abroad are restricted to such exports as the Comisión de Energia Atomica deems to be in the public interest. Production in 1963 was the highest since 1959.

NONMETALS

Barite.—Barite produced principally in the Provinces of San Juan and Neuquén supplies most of the well-drilling needs of the domestic petroleum producers and part of the similar requirements of Bolivia. Production has fluctuated with the slight variation in demand.

Borates.—Annual domestic requirements for borax are roughly 10,000 tons, and excess production of the source minerals tincal and ulexite, amounting to 5,410 tons in 1963, is exported. Reserves are extensive in five major deposits in Jujuy and six in Salta. Cía. Productora de Boratos and one other firm are the leading producers. Borate minerals are utilized in Argentina in manufacturing enamels, varnishes, glass, pottery, soap, toilet articles, tubes for conveying illuminating gas, straw hats, and textiles.

Cement.—An abundance of limestone, clay, and gypsum, as well as a usually adequate supply of fuel, permitted the establishment in 1913, and expansion, of a cement industry at rates generally commensurate with the steady growth of domestic demand. By 1963, 7 companies and the Argentine Government were operating 14 plants well distributed at or near 10 cities in 8 provinces. The plants had a total of 7,344 employees. Foreign trade has been relatively light and well balanced between exports and imports.

The most important producer was S. A. Loma Negra, which shipped 997,500 metric tons from its Barker, Loma Negra, and Frías plants. Others, in descending order of 1963 output, were Corporación Cementera Argentina, S.A., which shipped 385,696 tons from its Papinas, Kilómetro 7, and Capdeville plants; Compañí Sudamericana de Cemento Pórtland (Juan Minetti & Sons) with 327,659 tons from its Dumesnil, Panqueua, and Campo Santo plants; Compañía Argentina de Cemento Pórtland (a subsidiary of International Cement Corp., which also owns the Lone Star Cement Co.) with 541,346 tons from its Sierras Bayas and Paraná plants; S. A. Calera Avellaneda with 177,806 tons from its single V. C. von Bernard plant at Olivarría; the Argentine Government with 50,137 tons from its plant at Comodoro Rivadavia; and Yalu, S.A., with 30,869 tons from its newly established plant at San Juan.

[1] Plant shipments.
[2] Government owned.
[3] Plant started operating Mar. 28, 1963.

Pegmatite Minerals.—Mines of the pegmatite zone, described under beryl, yield as coproducts Argentine's total output of feldspar, lithium minerals, mica, quartz, and some of the fluorspar. Most of the fluorspar is found in veins with phyllite in Córdoba and San Luis—leading producing provinces—Catamarca, La Rioja, Mendoza, Rio Negro, and San Juan.

Salt.—Argentina is self-sufficient in its production of salt and normally has had a modest excess available for export. Reported production in 1963 was far below the preliminary estimate of 600,000 tons and is suspected of being incomplete.

Production is of three types: (1) Derived from solar evaporation of landlocked lakes fed by intermittent streams, chiefly in the Provinces of La Pampa, San Luis, Buenos Aires, and Córdoba; (2) mined as rock salt in the Provinces of Salta and Neuquén; and (3) derived from brine wells tapping subsurface saline deposits in the vicinity of El Tembo, Province of Tucumán. The three types are listed in the order of importance, with the first representing the bulk of production. Recovery of salt by the solar evaporation of sea water, a standard method elsewhere, is not practiced in Argentina.

Sulfur.—With the closing of the most important small producer in 1961, the production of sulfur in Argentina fell almost entirely in the control of Fabricaciones Militares, the Government military factories establishment, which refines the sulfur produced from its Azufre del Norte mine in the Province of Salta. Fairly uniform production at higher than world prices has satisfied less than half the normal de-

Digitized by Google

mand, the remainder having been made up by imports and production by Sulfacid, S.A., of sulfuric acid from zinc sulfide concentrates.

In addition to the exploited resources in the high mountains of Salta and Mendoza, relatively untouched deposits of sulfur occur in Jujuy and San Juan. Major domestic consumers of sulfur, largely as sulfuric acid, have been the petroleum refineries, tanneries, munition factories, plastic and rayon plants, sugar refineries, and miscellaneous chemical industries. Crude sulfur is consumed in the rubber, insecticide, and other industries.

MINERAL FUELS

Coal.—The increased usage of natural gas and fuel oil for industrial purposes reduced Argentine consumption of bituminous coal from the 1-million-ton level of 1960–61 to approximately 830,000 and 970,000 tons, respectively, in 1962 and 1963. Imports in 1963 (768,940 tons) were 157,000 tons greater than in 1962 but 447,000 tons, or 37 percent, less than in 1961. In the same 3-year period, mine production declined 40 percent. The ratio of imports to mine production was 3 : 5 in 1961, 2 : 2 in 1962, and 3 : 7 in 1963.

Argentina has a few small coal deposits in La Rioja, Neuquén, San Juan, and Rio Negro, but its most important resource and production area is in the foothills of the Andes at Rio Turbio, in the extreme southwestern corner of Santa Cruz. All the mines are operated by the Government agency YCF (Yacimientos Carboníferos Fiscales). Reserves in the Rio Turbio area have been estimated between 300 and 400 million tons of low-calory, high-ash coal. Shortages of labor, electric power, and machinery, and the difficult problem of transportation by rail to the port of Rio Gallegos, by boat to northern ports, and in some cases again by rail to consumption centers have raised delivery cost higher than that of imported coal, and an operating deficit of M$N2 billion in the 1962–63 fiscal year. The principal consuming outlets have been the Government-owned electric power companies, national railways, and SOMISA steel mill.

Petroleum.—Appraisal of developments of any single year in Argentine exploitation of its petroleum resources is difficult without a framework of the historical background, which was outlined by Edward V. Lindburg, Economic Officer, U.S. Embassy, Buenos Aires, in a State Department Airgram of May 23, 1963, as follows:

BACKGROUND OF PETROLEUM INDUSTRY

While searching for water to supply the needs of the small town of Comodoro Rivadavia, a Government well drilling team discovered oil on December 13, 1907. From 1907 to 1935 the Government, through YPF (Yacimientos Petroliferos Fiscales) and its predecessor agencies, competed freely with private companies (principally Esso and Shell) which were granted oil concessions in the 1920's. From 1935 to 1958, because of political and nationalistic considerations, the development of the Argentine petroleum industry was the exclusive domain of the Government. During this period no new concessions were granted, neither to Argentine nor to foreign companies, although the private companies were allowed to develop the concessions obtained in the 1920's.

The exploration and development of new petroleum areas was reserved by law entirely to YPF. However, during this period Argentina's petroleum needs were growing far faster than they could be met through YPF's exploration and development efforts, because of technical and financial inadequacies in YPF.

Digitized by Google

Constantly increasing imports of crude petroleum and petroleum products were necessary to satisfy the energy needs of Argentina's developing economy. These imports were an increasing burden on the balance of payments. The cost of petroleum imports, both crude and products, reached its maximum in 1958—about $250 million.

It was against this background that the newly-elected President Frondizi formulated a politically acceptable solution in July 1958. He started his "Battle of Petroleum" program by inviting foreign and domestic petroleum companies to bid, not on concessions, but on exploration and development contracts with YPF under which the companies bear the risks and expenses in prospecting in their allotted areas throughout Argentina and deliver any crude oil that may be found to YPF at contractual prices, averaging $11 per cubic meter. Since 1958 only three companies have delivered to YPF significant amounts of crude petroleum—Pan American Argentina Oil Company, a subsidiary of Standard Oil Company (Indiana); Argentina-Cities Service Development Company, which took over the Carl M. Loeb, Rhodes & Co. contract; and Tennessee Argentina S.A., a subsidiary of Tennessee Gas Transmission Company, Houston, Texas. These three companies today produce approximately 30 percent of Argentine crude petroleum, while YPF and its contract drillers produce about 70 percent. ASTRA, an Argentine company, Shell (Royal Dutch, Shell subsidiary) and four U.S. firms, including Esso, have yet to find significant quantities of petroleum under their contracts. Since 1958 these companies have invested about $200 million under their contracts.

DEBATE OVER OIL CONTRACTS

There are three types of contracts under which the foreign (mostly U.S.) oil companies work with YPF—exploration and development contracts, well drilling contracts, and oil well service contracts. There is no controversy over the service contracts under which several companies (Petro-Tech, Halliburton, Delta, Schlumberger, and Atlas) perform technical well services such as logging, perforating, coring, etc. Some criticism has been leveled at the drilling contracts—especially that the cost of $20 per meter is too high, and that YPF is contracting for too many wells at one time. Under these contracts the drilling companies (Southeastern, Kerr-McGee, SAIPEM) drill wells when and where directed by YPF.

The major volume of criticism has been directed at both the legal validity and the desirability of the exploration and development contracts. The contracts were attacked by the National Committee of the UCRP (Unión Cívica Radical del Peublo) and defended by the UCRI (Unión Cívica Radical Intransigente—Frondizi's party) and the Secretary of Energy and Fuels. Openly opposing the Government's petroleum policy, the President and several directors of YPF debated the validity of the contracts at YPF Board meetings during 1962, and the Board eventually decided to request the legal opinion of the Attorney General of the National Treasury. This request was refused by the Government and the debate came to a head on December 13, 1962 (Petroleum Day) when YPF President Fitte, in a nationally broadcast speech, attacked the Government's petroleum policy and described the contracts as "unjust and burdensome for YPF and for the nation". His resignation and those of three YPF directors who supported his position were accepted by the Government on December 28 (Fitte has been replaced as YPF President by José L. J. Mazzaferri). Although the debate on the contracts ceased within YPF, it will be continued during election year 1963 both by sincere opponents of the contracts, as well as by those with political, personal or ideological axes to grind.

Frequently overlooked is the fact that under the contracts YPF always retains title to the oil—whether below or above ground. Undoubtedly the attacks on the contracts will strengthen YPF's hand when it decides to renegotiate them. Several of the foreign oil companies have expressed publicly their willingness to engage in reasonable and responsible negotiations with a view to modification of some clauses of their contracts.

* * * * * * *

Perhaps the major problem in the current development of Argentina's petroleum industry is financial, i.e., how a country in an economic depression, with large budgetary deficits and a growing balance of payments problem, can pay for

Digitized by Google

the work which must be done by private companies, either foreign or domestic, to enable Argentina's underground petroleum resources to be developed so as to satisfy the enery needs of the nation. The development and utilization of Argentina's petroleum resources is comparatively expensive because of the heavy qualities of Argentine crude, the low yield per well-year, and the distance from production to consumption centers.

At the close of 1963 the contracts of the service companies and of the Pan American Argentina Oil Co. and the Shell Production Co. of Argentina apparently were still operative, but Decrees No. 744 and 745 of November 15 annulled the drilling, exploitation, and pipeline contracts signed in the years 1958 through 1961 with the following companies: Argentina Cities Service Development Co. (ex-C. M. Loeb Rhoades & Co.); Astra, Compañí Argentina de Petróleo S.A.; CADIPSA—Compañía Argentina para el Desorrollo de la Industria del Petróleo y Minerales; Continental Oil Co. of Argentina; ESSO S.A.P.A., Esso Argentina, Inc.; SNAM (ex-Saipem (E.N.I.)); Southeastern Drilling Co. of Argentina, S.A.; Tennessee Argentina, S.A.; Transworld Drilling Co. (ex-Kerr McGee Industries, Inc.); and Union Oil Co. of California (operating agent: Cabeen Exploration Co.).

Decree 744 authorized YPF, the state oilfields entity, to take such steps as it might deem appropriate for the normal supply of fuel for the country.

Crude petroleum production in 1963 was 97,221,000 barrels; 64,917,000 (66.8 percent) was obtained by YPF, 29,595,000 (30.4 percent) from fields formerly operated by the contractors but recovered by YPF in November, and 2,709,000 (2.8 percent) from the four old concession areas operated by Shell, Petroquímica, Astra, and El Sosneado. Drilling completed during the year was as follows:

Wells:	*Drilled by YPF*	*Drilled by contractors*	*Total*
Field	86	504	590
Exploration	59	39	98
Outpost	109	--------	109
Total	254	543	797

Whether YPF is equipped to maintain a statisfactory balance between exports and imports with an expanding domestic demand for petroleum products remains to be tested.

The distribution of crude petroleum production by provinces in 1962 and 1963 has been reported as follows, in thousands of barrels:

Province:	*1962*	*1963*
Chubut	22,919	21,649
Santa Cruz	37,104	40,017
Neuquén	6,044	5,163
Rio Negro	34	23
Mendoza	17,694	18,013
Salta	8,458	6,537
Tierra del Fuego	5,952	5,766
Total	98,205	97,168

Crude is processed at the La Plata, San Lorenzo, Luján de Cayo, and Dock Sur-Avellaneda plants of YPF; the Compana, Bahía Blanca, Manuel Elordi, and Dadin plants of Esso Refinadora de Petróleo; the Dock Sur-Avellaneda plant of Diadema Argentina S.A. de Petróleo;

Digitized by Google

the Comodoro Rivadavia plant of Petroquímica; the Salta plant of Chachapoyas; the Bahía Blanca plant of La Isaura, S.A.; the Neuquén plant of Plaza Huincul; the Lomas de Zamora plant of Condor S.A. Petrolera Argentina; the Dock Sur-Avellaneda plant of Lottero y Papini Cía.; and the Quilmes plant of Ragor Cía., S.A. (Ramón Gerleri).

The Mineral Industry of Bolivia

By Frank E. Noe [1] and Sumner M. Anderson [2]

IN 1963 the gross value of mineral exports, indicative of approximate value of production (before deduction of realization and other costs) was placed at US$82,825,924 by the Bolivian Ministry of Mines and Petroleum. This was equivalent to 96 percent of the value of all 1963 exports (US$86,400,000) and represented roughly a 16 percent increase in value of 1962 mineral exports. Tin was by far the most valuable export commodity in 1963 accounting for US$57,369,314 or 66 percent of the value of all exports.

Bolivia has a significant position in the world production of three minerals—tin, antimony, and bismuth. In 1963 Bolivia was third in production of antimony and tin-in-concentrates, and fourth in bismuth; its share in the global production of these metals was 13.5 percent, 12.0 percent, and 7.8 percent, respectively. Bolivia also ranked fifth in production of tungsten, having 3.9 percent of the world output. It is in the Western Hemisphere, however, that Bolivia achieves its principal importance as a source of mineral supplies. It ranked first in production of tin and antimony, second in tungsten, third in bismuth, fourth in gold, fifth in silver and sulfur, sixth in lead, and seventh in zinc. Bolivia is handicapped in its competition for foreign markets by location of its mines at altitudes above 12,000 feet and corresponding transportation problems. As a land-locked nation it also bears heavy transportation costs through neighboring countries to reach ocean ports.

The mining industry has been historically, and is at present, the most important element of the Bolivian economy. The country is highly dependent commercially and financially on its mineral exports. Mineral production has contributed more than 90 percent of the foreign-exchange income, and the mining industry in the past has accounted, directly and indirectly, for more than half of the gross national product (GNP). In 1956 the industry directly accounted for about 47 percent of the GNP. From that time its contribution declined sharply to 16.2 percent by 1963, a figure exceeded, however, only by agriculture.

Although the mining industry dominates the economy of the country, only a small portion of its total output is consumed domestically. Domestic production of iron and steel products is extremely limited, and almost all consumption requirements are supplied by imports. Nonmetallic minerals are of little importance because the domestic

758-002—65——14

Digitized by Google

consumption of these commodities is small, and the high production and transportation costs preclude any sizable output of low-unit-price commodities for export. Bolivia is thus an exporter of mineral raw materials and an importer of semifinished and finished metal products, machinery, and equipment.

In addition to its important contribution of foreign exchange to the economy, the mining industry was the largest employer of salaried workers, even though about two-thirds of the population are engaged in agriculture. The mining industry (excluding petroleum) in 1963 employed about 45,000 people permanently and 30,000 more part-time.

Mines in the industry have been traditionally classified arbitrarily by volume of production as large, medium, and small. The only large mines are those of the former Patiño, Hochschild, and Aramayo enterprises which were nationalized in 1952. Since that time they have been managed and operated for the Bolivian Government by the Bolivian Mining Corp. (COMIBOL), which was established especially for that purpose. In 1963 COMIBOL contributed 61 percent of the gross mineral export value, including 68.6 percent of the total tin exports, 97 percent of bismuth, 86 percent of silver, and 81 percent of zinc. At the end of 1963 the COMIBOL work force in 20 operating mines numbered 25,524.

Medium-size mines are those that have a monthly output of not less than 5,500 kilograms of fine tin, 7,000 kilograms of tungsten, 20,000 kilograms of antimony, 20,000 kilograms of copper, or 15,000 kilograms of lead. Mines which do not meet the normal monthly minimum-production schedules are classified as small. In 1963 the small and medium mines, comprising the private sector of the industry, numbered about 2,100. These operations employed about 19,000 people or approximately 42 percent of the total permanent workers in the mining industry. The value of exported mineral products of these medium and small mines for 1963 was approximately US$31,352,000, which represented 38.9 percent of the total value of the output of the mining industry, excluding petroleum. During 1963 the private mining sector produced 99.9 percent of the gold, 98.4 percent of the antimony, 85 percent of the tungsten, 56 percent of the lead, 51 percent of the copper, 31 percent of the tin, and important quantities of zinc and silver.

Indicators of the general economy of Bolivia are presented as follows:

	1959	1960	1961	1962	1963
GNP in current prices million U.S. dollars	336	390	431	475	500
Population thousands	3,705	3,790	3,877	3,966	4,057
GNP per capita	91	103	111	120	123
Cost of living index, La Paz, 1958=100	120	134	144	152	151
Exports, gross million U.S. dollars	78	68	77	76	86
Mineral exports, gross million U.S. dollars [1]	69	60	69	70	81
Imports, gross million U.S. dollars	65	72	78	98	104
Gross mineral production, percentage of GNP [1]	20.5	15.4	16.0	14.7	16.2

[1] Excluding petroleum.

GOVERNMENT POLICIES AND PROGRAMS

In 1936 the Bolivian Mining Bank was created to promote the mining industry by granting credit; maintaining stores of supplies, tools, and machinery; and providing technical personnel to assist the medium and small mining companies. In June 1952 this organization was authorized as the sole purchaser and exporter of mineral products. The same decree also directed that the small and medium mining companies purchase all machinery and equipment from the bank. This decree, in effect, nationalized the mining industry. A few months later, in October 1952, purchase of the production of large mines was passed from the mining bank to the Bolivian Mining Corp. (COMIBOL) by a decree which established COMIBOL for operating and managing the expropriated properties of Patiño, Hochschild, and Aramayo.

Finally in an attempt to control runaway inflation, the Government in December 1956 made important changes in its policy toward the private mining industry. It decreed that:

1. Production of the medium mines could be sold to the highest bidder, whether Mining Bank or private ore buyers.
2. Production of the small mines would continue to be purchased and marketed exclusively by the bank.
3. Private miners could purchase their machinery and supplies from any source, rather than exclusively from the Mining Bank.

At the same time the Government decreed that the net proceeds from all mineral sales, after deduction of realization costs and royalty, would revert to the possession of the miners and that the miners were to pay the Government a royalty on production in lieu of all other taxes. This policy exists today and has resisted all attempts by the associations of small and medium miners to lessen the control of the Government and the Mining Bank over the private sector.

In 1963 the U.S. Agency for International Development financed two technical groups to assist the private mining sector. One of these technical groups is cooperating with the National Department of Geology, which is primarily engaged in mapping mineralized zones in Bolivia and in offering technical geologic assistance to the small miners. The other group was assigned to the Mining Bank and to recommend changes in the structure of the bank and to assist in reorganization of that entity.

Although the Government expressed interest in a reorganization of the Mining Bank, internal political pressures nullified efforts to accomplish the basic changes required to aid the growth of the private sector of the mining industry. Throughout 1963, the bank continued to operate with the complex structure and ineffective organizational framework that had been devised at its inception. Overhiring and the financial support of uneconomic ventures brought the bank to a precarious financial position that completely paralyzed its ability to render effective financial and technical aid to the small mines.

Bolivian and American experts discussed and proposed modifications of the Mining Code with a view to making it more attractive to private capital. The high-mineral export taxes also were studied, and recommendations for changes were prepared for submission to the Government.

Digitized by Google

The Government, through the National Department of Geology, continued a joint geological exploration program with United Nations technicians. Another joint project between Bolivia and the United Nations calls for creating a national Institute of Mining and Metallurgical Investigations for increasing mine production, improving beneficiation practices, and investigating methods of refining. The location of the new Institute and the form of the Bolivian contribution to it had not been definitely determined by the end of the year.

The COMIBOL mineral production record reveals a sharp drop in tin output following nationalization of the mines. In 1952, COMIBOL produced 27,347 metric tons of fine tin. The following 10 years, production gradually declined. In 1961, the overall output of COMIBOL amounted to 14,830 tons of fine tin, a reduction of 48 percent. Since COMIBOL produces more than 61 percent of Bolivian mineral exports, which in 1963 amounted to 96 percent of the value of all Bolivian exports, the decline in COMIBOL production has been a matter of serious concern to the Bolivian Government.

The chief causes in the decline of production were:

1. Management inability to cope with the political power of the labor unions. Labor had power to veto management decisions and operations and at times even interfered in administration.

2. Decapitalization of COMIBOL, which resulted from rampant monetary inflation from 1952 to 1957 and the official exchange policy of the Bolivian Government. While the unofficial exchange rate rose from 190 Bolivianos (Bs) per dollar to Bs12,000 per dollar during that period the official exchange rate remained at Bs190 per dollar. Labor and other costs rose with the unofficial exchange rate, but the COMIBOL gross income did not, since it was obligated to sell all tin produced through the Central Bank at the official exchange rate of Bs190 per dollar. In this manner it is estimated that COMIBOL from 1952 to 1956 lost $120,500,000 and, in the process, totally decapitalized itself.

3. Lack of reinvestment in machinery and in exploration. Because of decapitalization, COMIBOL had no capital to do either.

4. Inadequate management to meet the technical, operational, financial and accounting requirements of a very large and complex mining operation. With the withdrawal of the former owners following nationalization, COMIBOL lost most of its experienced managers and technicians.

Seeking to correct the problems involved, a "Memorandum of Understanding" was negotiated on June 9, 1961, between the U.S. Agency for International Development, the Inter-American Development Bank, and the Federal Republic of Germany. Under this agreement a three-phase rehabilitation plan known as Operation Triangular was undertaken. An overall investment of US$37.75 million to be disbursed during a 3-year period was envisaged. This did not include funds for working capital, the need for which was recognized but not included in the estimate. Nevertheless, funds required for working capital have been furnished exclusively by the U.S. Agency for International Development.

Delay in the administration and coordination of the international operation and consequently in the disbursement of funds, as well as

Digitized by Google

the late arrival of the necessary equipment and supplies at the mines, forced a change in the original concept of the rehabilitation plan. The original 3 years became three phases, each lasting 18 months, with the second phase scheduled to end on or about April 1964. The first and second phases of the Triangular Operation were largely devoted to reorganization and restocking of spare parts and equipment. Owing to the time lag between ordering equipment and its arrival at the mine sites, there were still about $2 million worth in transit at the end of 1963. However, most direct mining and milling equipment had been renewed, and the warehouses had nearly enough spare parts and materials for 2 years.

During the first two phases loan funds were received as follows:

(In millions of dollars)

Triangular Operation basic agreement		US$37.75
First phase	US$14.75	
Second phase	US$12.38	
Total phases		US$27.13
Total available		US$10.62

In addition to funds which were normally financed under the Triangular Operation the following loans were negotiated in order to finance the funds required for working capital:

(In millions of dollars)

U.S. Agency for International Development	US$16.68
Banco Central de Bolivia	0.50
Smelters	1.43
Total	US$18.61

The funds received during the first two stages of the Triangular operation have enabled COMIBOL to increase production and to improve its economic structure. In 1963, if there had been no strikes or other disorders to interrupt COMIBOL mining activities, the total production of COMIBOL mines would have reached 16,500 metric tons of tin or about 10 percent more than the average of the 3 previous consecutive years. This production was not reached, however, because of Communist-led strikes during July and August. In all previous strikes since nationalization, whether justified or not, labor had been paid for strike time. The refusal of COMIBOL to pay for the strikes in 1963, combined with the strong stand taken by the Government in the hostage incident in December, have definitely discouraged strike abuses in the mines. Public opinion and the daily newspapers opposed the general strikes and were hostile to union strike leaders. The Government made progress in diminishing the power of extremists and has been strengthened in this by the important financial help given under Operation Triangular. However, the administrators of COMIBOL did not regain the right to manage operations to the extent that is considered necessary. Although considerable progress was made in management-labor relations, it was still not possible to implement in full the measures needed to achieve technical and eco-

Digitized by Google

nomic rehabilitation of COMIBOL operating units. However, a very important step was taken in August when, despite strong objections by the unions, the Government suspended the right of labor to veto the decisions of management.

The mines have been equipped to produce more ore but there is still much to be done in improving tin recovery by the present concentrating plants. To improve recovery COMIBOL and the Triangular Operation, during 1963, sponsored metallurgical research in the United States, Canada, England, West Germany, and Holland. At the same time substantial additions of equipment were made to COMIBOL metallurgical laboratories in Oruro, and a diversified research program has been conducted in this laboratory.

Costs involved in producing 1 pound of tin have been lowered from $1.37 in 1962 to $1.29 in 1963. Cost reductions were attributable to the increased quantity of tin that could be produced because of the additional equipment and spare parts provided in the first and second phases of the Triangular Operation and to the mining of slightly higher grade ores owing to better geologic control, instituted by technicians brought to COMIBOL by the rehabilitation plan. These costs may be reduced further by good management to the level of costs in the private medium mine sector, which were $1.01 in 1963. The average price received by COMIBOL from selling tin concentrate in 1963 was US$1.124 per pound of contained tin, indicating a loss of US$0.216 per pound in its tin operations. The future outlook indicates that there are favorable possibilities of COMIBOL increasing its mineral production and reducing its overall operating costs.

SOURCE MATERIAL

Mineral production statistics for the whole mining industry are not available. COMIBOL issues relatively accurate figures for production, metallurgical results, and exports. The small and medium mines, constituting the private sector of the industry, do not report production. However, the total exports of the Mining Bank, which buys all production of the small mines, and of the medium mines, which sell to the highest bidder, may be regarded as being representative of the production of the private sector. For most minerals there is no domestic consumption and, because the small and medium mining entities are usually short of capital, there is no significant inventory buildup of unsold minerals. Only in production of gold and silver is there a substantial difference between production and export because of domestic consumption and holding of inventories.

Preliminary export figures are prepared by the General Directorate of Mines (Direccion General de Minas) of the Ministry of Mines and Petroleum and usually are available approximately 3 months after the end of the reporting period. Official statistics of exports and imports are prepared by the Ministry of Finance and Statistics (Ministerio de Hacienda y Estadistica). The official export figures for any given year are usually available within 6 months following the end of the year. The final official import statistics are published in the annual Import Statistics (Importaciones) by the General Directorate of Statistics and Census of the Ministry of Finance (Direc-

Digitized by Google

cion General de Estadistica y Censos, Ministerio de Hacienda). However, this volume is not available until 2 or 3 years after the period in question. The most recent detailed import statistics available from this source are for the year 1961. However, the system of commodity classification was changed during that year, and the imports for the second half of the year are detailed in an entirely different manner from those of the first half of the year. Therefore, import data shown in this report for 1961 should be considered as approximate only, having possible duplications or omissions within the commodity classifications. Petroleum statistics have been supplied by the American Embassy in La Paz, with production for 1962 and 1963 adjusted to data published in the Bulletin of the American Association of Petroleum Geologists, August 1964. This combination of sources tends to give Bolivia an unreliable record of statistical accuracy. General economic data were obtained from the Economic Data Book for Latin America prepared by the U.S. Agency for International Development. Basic information has been obtained from field observations and conversations of the U.S. Bureau of Mines mining engineer in Bolivia with representatives of COMIBOL and the Inter-American Development Banks Advisory Group to COMIBOL. Reports prepared by COMIBOL for the Inter-American Development Bank have also contributed much information.

PRODUCTION

Production statistics presented in the following table represent actual COMIBOL production plus exports by the small and medium mines and the smelters. In addition to the nonmetallic minerals reported, salt and sodium carbonate are produced but statistics on these industries are not collected.

[1] COMIBOL production data plus exports by small and medium mines and smelters. Figures differ slightly from those in volume I which uses total exports as indicative of approximate production.
[2] Exported by small and medium mines.
[3] Data not available.
[4] Contains unspecified amount of tin reported also in tin-in-concentrate production. Total mine production is tin-in-concentrates plus an unknown portion of the tin in refined metal, solder, and drosses

TRADE

Bolivia has had an unfavorable trade balance for many years, primarily because of heavy imports of food and declining mineral exports. In 1963, however, with mineral exports at a 7-year high, imports were also inflated by the arrival of large quantities of spare parts and replacements for worn out and obsolete equipment in COMIBOL mines and mills. The normal purchase of 68 percent of Bolivian tin makes the United Kingdom the principal buyer of Bolivian mineral raw material exports. Other important consumers of Bolivian minerals are the United States, West Germany, and the Netherlands. The United States is the primary source of Bolivian imports and in 1963 supplied approximately 48 percent of the total. West Germany, Japan, the United Kingdom, and Argentina also supplied important quantities of food and manufactured goods. Normally, detailed import data are not available in published form for several years follow-

Digitized by Google

ing the end of the period; however, in 1963 a new and modern mechanized system of tabulating custom data was installed, and it is anticipated that detailed foreign trade statistics will become available with less time lag.

COMMODITY REVIEW

METALS

Antimony.—Antimony is produced and exported as handpicked lumpy ore and gravity concentrates. A small quantity of concentrates also is produced by flotation. The largest operator is the Empresa Minera Unificada, S.A. (EMUSA), which regularly produces between 42 and 47 percent of the total production. In 1962, EMUSA produced 2,836 metric tons of antimony in concentrates. In August 1962 COMIBOL initiated treatment of frankeite, a lead-antimony-tin-silver sulfide in a new 100-ton-per-day flotation mill at the San José mine in Oruro. Production was on a reduced scale until September of 1963, when the plant began operation at full capacity. The frankeite mill produced all COMIBOL antimony output in 1963—amounting to 107 metric tons obtained from ore averaging 250 grams per ton of silver, 2.9 percent lead, 0.8 percent antimony, and 0.5 percent tin. Complex concentrate containing 4,500 grams per ton of silver, 47 percent lead, 16 percent antimony, and 3.4 percent tin is exported to Europe. In 1963 a survey of Bolivian antimony resources was conducted under the sponsorship of the U.S. Agency for International Development. The survey reported an estimated antimony reserve of 1,530,213 tons of ore, having a metal content of 134,097 tons of antimony metal and an average grade of 8.78 percent antimony. This tonnage is distributed between dumps and mine ore in the following proportion: Mine ore 925,150 tons, containing 10.98 percent antimony, and dump ore 605,063 tons containing 5.38 percent antimony. The mine reserves are inferred and only the dump ores are measured reserves.

Bismuth.—The Tasna mine of COMIBOL was the principal producer of bismuth, accounting for 238 tons or 93 percent of the domestic production in 1963.

Digitized by Google

Copper.—The Corocoro mine of COMIBOL was the largest copper producer, and production was mainly as metallic copper. In 1963, Corocoro mine produced 1,360 tons. The only other production of copper by COMIBOL was recorded at the Tasna mine, where 104 tons of copper was separated from bismuth by flotation methods. The Japanese firm, Nitto Mining Co., was the second largest producer of copper, having a 1963 output of 1,105 metric tons from the Chacarilla mine.

Gold.—Gold production recorded an appreciable increase from 35,034 ounces in 1962 to 153,019 ounces in 1963. The increase was principally in output of the gold cooperatives on the Tipuani River, from 1,536 kilograms to 2,494 kilograms. A decrease in production of the South American Placers, Inc., from 1,077 kilograms to 997 kilograms was due to breakdowns of its dredge. At the end of the year the Tidewater Oil Co. was negotiating with the Bolivian Government for placer ground formerly held by the Bolinca Co.

Lead.—The largest individual lead producer was the Animas mine of COMIBOL, accounting for approximately 25 percent of total Bolivian production. In 1963 it produced 4,788 metric tons. The Tatasi mine produced 1,650 tons; the San José mine, 1,258. Breakdown of production by individual small and medium mines is not known.

Mercury.—Mercury is recovered sporadically from old patio-process areas. Production for 1963 was probably an accumulated total for several years.

Silver.—Silver, the second most valuable mineral export, is produced in association with lead, zinc, and tin. The Animas mine of COMIBOL was the primary source of Bolivian silver in 1963 producing concentrates containing 86.9 metric tons of silver. The San José mine and the Tatasi mine also produced important amounts during 1963, 17.9 and 10.6 metric tons, respectively.

Tin.—The 1963 COMIBOL tin production of 15,150 long tons was only slightly higher than the 15,020 long tons produced in 1962. COMIBOL exports, however, increased from 14,721 long tons in 1962 to 15,693 long tons in 1963. It is noteworthy that about 67 percent of COMIBOL 1963 production was mined and milled through COMIBOL facilities; the remainder was mined by cooperative groups and contractors who work in or near COMIBOL mines and sell their production to COMIBOL. Tin exports by the private sector increased about 2.5 percent, including an 18 percent increase in exports from medium miners and a 5 percent decline by small miners.

TABLE 4.—Exports of tin by groups

(Long tons of contained tin)

Group	1956–60 (average)	1961	1962	1963

Digitized by Google

The average mining and realization cost for COMIBOL, excluding export taxes, decreased from $1.37 in 1962 to $1.34 in 1963. The comparison of the 1963 monthly averages for the five major COMIBOL mines and COMIBOL as an entity is shown in table 5. The same cost in private mining amounted to $1.01 per pound of tin in 1963. The high-production costs in the nationalized mines have been attributed to ineffective management and to low labor productivity stemming from a lack of discipline and excess personnel.

The Fundicion de Estaño Oruro (Bolivia), S.A., more commonly known as the Peró smelter, added three Schmitz and Apelt remote-controlled rotary furnaces during the year. The smelter theoretical capacity was raised to 5,000 tons of tin per year, based on consumption of concentrates containing a minimum of 50 percent tin. The feed to the smelter is primarily concentrates from the Colquiri mine of COMIBOL.

TABLE 5.—1963 monthly average tin production data for major COMIBOL mines

Mines	Ore grade, percent tin	Production, long tons fine tin	Cost per pound [1]		Mill recovery, percent	Percentage of COMIBOL output
			Mining	Total		
Catavi	0.55	291	1.46	1.62	49.6	23
Huanuni	.89	217	1.02	1.18	62.9	17
Colquiri	.83	180	1.31	1.54	50.5	14
Unificada	1.29	130	.87	1.27	51.0	10
Caracoles	1.74	84	.69	.87	74.5	7
COMIBOL average	.76	1,283	1.02	1.34	51.5	100

[1] Mining costs include mining, milling, and depreciation. Total costs include mining, milling. depreciation, transportation, handling, insurance, and smelting. Export taxes are not included. These ranged in 1963 from 5 to 18 cents per pound of tin.

Tungsten.—Tungsten producers continued to be plagued by decreased demand and low prices during 1963. Output declined to the lowest point in the last decade.

Zinc.—Production by the small and medium mines, responding to favorable increases in the market price of zinc during the year, was 866 tons, an increase of 367 percent over their 1962 production. The production of COMIBOL, however, declined slightly from 3,398 to 3,363 tons. The Overseas Mineral Resources Development Co., a Japanese firm, announced at the end of the year that it hoped to sign an agreement with the Bolivian Government for the joint development of the Matilde zinc mine. If agreement is reached a new firm for development of the mine would be established by the Japanese firm and COMIBOL.

NONMETALS

Cement.—About 98 percent of Bolivian requirements for cement was supplied by a plant at Viacha, privately owned by the Sociedad Boliviana de Cemento, and a plant at Sucre, owned by the Government and operated by the Corporacion Boliviana de Fomento. The Viacha plant was established in 1926 and the Sucre plant (whose principal customer is COMIBOL) in 1961. Production has been divided as follows:

Digitized by Google

	Quantity, metric tons	
	1962	1963
Viacha plant	27,320	31,754
Sucre plant	22,109	24,490
Total	49,429	56,244

Sulfur.—Export of 9,950 tons of sulfur marked a new high for this mineral element. The previous peak of 9,246 metric tons was reached in 1951. Sulfur was mined from volcanic deposits near the town of San Pablo de Napa, Department of Potosi, and was exported to Chile.

MINERAL FUELS

Natural Gas.—Production of natural gas was reported at 5,110 million cubic feet in 1962 and 5,948 million cubic feet in 1963, with nothing to indicate whether these figures represented gross or commercial production.

Petroleum.—Yacimientos Petrolifera Fiscales Bolivianos (YPFB), a Government entity, was created in December 1936 to undertake the exploration and possible development of vast areas of eastern Bolivia, considered to have oil bearing possibilities. The only actual petroleum assets then existent were the proven Camiri, Sanandita, and Bermejo fields and two small refineries that were acquired for YPFB by Government seizure from the Standard Oil Co. of Bolivia in March 1937, the first of such seizures in Latin America. Between that time and the end of 1963, YPFB expanded the development of these fields and of later discovered productive structures in the Guairuy, Toro, Camantindi, and Los Monos fields. Production expanded, but earnings were insufficient to finance an adequate exploration and exploitation program, and by the mid-50's the door had again been opened to exploration and development by private companies. The Bolivian Gulf Oil Co., which began operating in Bolivia in 1956, loaned YPFB US$5 million in 1957 to build a branch extension of its Cochabamba-La Paz pipeline from Sicasica to Arica, Chile, to facilitate petroleum exports from the Pacific port. Crude production reached a peak of 3,575,000 barrels in the same year, and the pipeline has received no appreciable use. Current production is maintained by using various techniques to increase recovery from wells that are approaching exhaustion, including gas injection, gas lift, and hydraulic fracture. By these methods, production by YPFB is expected to meet the anticipated 5-percent yearly increase in domestic demand for gasoline through 1967, after which production will drop sharply unless new fields are discovered. Of the many interests that have invested millions of dollars in exploration, six private companies and company partnerships still held concessions at the end of 1963; others were relinquished in that year. Only two had found commercially exploitable oil and remained active.

The Bolivian Oil Co. was the first and larger producer, but its reserves in the Madrajones field adjoining the Argentine border appear to be approaching exhaustion. The gas-to-oil ratio has been relatively high, and in October 1962 the company began piping gas to Argentina. These exports amounted to 319 million cubic feet in the last quarter of 1962 and 1,957 million cubic feet in 1963. All of the

Digitized by Google

crude petroleum produced in 1962 was sold to YPFB. In 1963 YPFB purchased 64 percent (83,462 barrels) of the Madrajones production, and the remaining 36 percent (46,082 barrels) was exported to Argentina.

The Bolivian Gulf Oil Co., with little production so far, has had the best success in exploration and holds the brightest potential for the future, with 46 shut-in wells capable of producing oil or gas but awaiting pipeline outlets for disposal of both products. Delineation and evaluation of its three fields continued, following the discovery of oil at Caranda (1960), oil and gas-condensate at Colpa (1961), and gas-condensate at Rio Grande (1962). Small quantities of oil have been sold to the YPFB topping plant at Santa Cruz. Developed reserves of both oil and gas are said to be very large. The company has been negotiating with the Government relative to construction of a pipeline from the Caranda field to join the State-owned pipeline from Sicasica to Arica.

On June 6, 1962, a Presidential supreme decree transferred all potentially attractive petroleum areas not then under concession (including 1960 concession areas subsequently renounced by private industry) to the fiscal reserve.

TABLE 6.—Crude petroleum production distributed by company and field

(42-gallon barrels)

Company and field	1959	1960	1961	1962	1963
Yacimientos Petrolifera Fiscales Bolivianos:					
Camiri-Guairuy	2,657,345	2,640,823	2,249,464	2,043,209	2,678,531
Bermejo-Toro	481,409	449,566	438,955	498,954	401,741

Bolivian Oil Co.: Madrajones		463,678	282,442	188,408	129,505
Bolivian Gulf Oil Co.: Caranda				125,938	[1] 116,318
Total	3,170,128	3,574,123	2,988,767	2,917,100	3,400,915

[1] Production through May, wells capped during last 7 months.

All the unexported crude was treated in the YPFB seven petroleum-processing facilities. Pipelines delivered crude from the producing fields to their installations, and distributed finished products for domestic use to Tarija, Santa Cruz, Potosi, Oruro, and La Paz and for export to Argentina. Total domestic consumption was 2,702,229 barrels of crude and 2,409,522 barrels of refinery products in 1962 and 2,695,164 barrels of crude and 2,513,970 barrels of refinery products in 1963.

The Mineral Industry of Brazil

By Garn A. Rynearson [1]

BRAZIL makes significant contributions regularly to the world supply of several mineral commodities. In 1963, Brazil ranked first in world production of quartz crystal and beryl; second in sheet mica; third in manganese ore, monazite, and columbium and tantalum concentrates (including pyrochlore); fourth in zirconium minerals; and about tenth among listed world producers of iron ore, lithium minerals, tungsten mineral concentrates, and feldspar. All of these items except feldspar were produced in excess of domestic needs and exported in crude or processed forms to help fulfill the requirements of other industrial countries. Output of quartz crystal, beryl, sheet mica, and manganese ores each represented more than 5 percent of the world totals. In addition, Brazil produced a large share of the world supply of several semiprecious gemstones.

The total value of mineral products mined in Brazil is estimated at approximately 61.7 billion cruzeiros for 1961 and 83.1 billion for 1962, representing about 1.75 and 1.5 percent of the gross domestic product for those years. These estimates include the manufacture of cement and lime (about 45 percent of the total) and crude oil production (about 25 percent) but exclude sand, gravel, and common clay because quantity and value of their output are unavailable. Refining of petroleum and reduction of metallic ores and concentrates to metals, except gold and silver, also are excluded. Crude oil output was assigned a value based on average export value during the year. Value added by reduction of ore to primary metal form and by the export of mineral commodities (f.o.b. value) amounted to approximately 36.6 billion cruzeiros in 1961. Basic data available for 1962 are incomplete, but value added by production of metal and export of minerals for that year was roughly 49 billion, if the ratio of increase was about the same as in 1961. Petroleum refining is not included in these estimates as available data are not strictly comparable with data on other products. In terms of U.S. dollars, estimated total cruzeiro value for the entire industry as qualified above equates roughly to 686 million for 1961 and 618 million for 1962.

Mineral raw materials are of prime importance to the country, as its economy has shifted rapidly from a predominantly agricultural base to one in which the industrial sector now contributes a share of the national income almost equal to that of agriculture. With a territorial area ranking it as the fifth largest country in the world, Brazil is favored with a huge but underdeveloped potential of mineral resources and, as the eighth most populous nation, its represents a large

[1] Physical scientist, Division of International Activities.

758-002—65——15

Digitized by Google

consumer market that is growing faster than the capacity to develop the resources. Brazil is deficient in known resources of some basic mineral raw materials, notably sulfur, potash, copper, silver, coking coal, and petroleum, which must now be imported in relatively large quantities to nurture industry and to sustain its expansion. Domestic production essentially satisfies current demand for salt, construction materials, most ceramic and refractory materials, and a few other industrial minerals, but the country still lacks adequate capacity to process sufficient quantities of domestic minerals to meet all its requirements of most ferrous and nonferrous metals, of mineral fertilizers, and of many mineral-based chemicals.

The mineral industry remained remarkably stable in 1963 despite political, economic, and social problems that beset the country during most of the year, but in general, it failed to attain predicted levels of productivity. An unchecked inflationary spiral caused the exchange rate of the free market cruzeiro to fall from Cr$795=US$1.00 in January to Cr$1,230=US$1.00 at yearend and the cost of living soared 80.6 percent. Under these circumstances, labor and distribution costs continued to rise and many domestic mineral producers found it difficult to compete with importers of foreign products. Some probably continued to operate only by virtue of the protection offered by government subsidies and strict import controls. Furthermore, a combination of leftist and nationalistic trends helped to create a climate that not only made new foreign investment unattractive but discouraged investment of private Brazilian risk capital as well, thus retarding much-needed expansion of the minerals and other industries.

SOURCE MATERIAL

Statistical data pertaining to the metal and mineral industries of Brazil are by no means complete or accurate for many commodities and simply are not available for others. Trade data compiled by the Serviço de Estatística Econômica e Financeira of the Ministry of Finance and data on the petroleum industry, compiled by the Conselho Nacional de Petróleo, are considered unusually reliable; but the latter are incomplete in that value of output is not included.

The Serviço de Estatística da Producão of the Ministry of Agriculture and the Conselho Nacional de Estatística (IBGE) collect official data on the production and consumption of ores, minerals, and metals. Theoretically, the system used should provide excellent statistical coverage, but some producers do not report, and some do not report completely the information required. Furthermore, production data compiled and reported by these agencies are intended primarily to record mine extraction of crude ores and reduction of major metals. They do not include the amounts of marketable mineral products that have been beneficiated by other than rudimentary methods such as hand sorting. For example, apatite ore and asbestos-bearing rocks are reported, but apatite concentrate and asbestos fiber are not, and in such cases, it is reasonably certain that data on ores and concentrates reported for different mines have been added together indiscriminately or unintentionally to obtain erroneous totals. Excluded also are data on metal content or other measurement of the

Digitized by Google

grade of ores. Some official data, therefore, are not representative of output as normally recognized in trade circles and merely present unknown portions of unknown totals without so indicating.

In compiling the table on production, an attempt was made to evaluate source data on each commodity shown. In most cases the official sources were judged more nearly complete and more consistent than unofficial sources. In a few cases other sources were used, such as the special studies made by the Banco Nacional do Desenvolvimento Econômico (BNDE) on lead and fertilizer materials and surveys made by the American Embassy and trade organizations. Production data on some commodities produced primarily for export are incomplete and less representative than export figures. Informed estimates based on various sources have been made to indicate order of magnitude of production for some commodities, but information available for others known to be produced is too meager or too unreliable to provide a basis for a meaningful estimate.

Inasmuch as official production data for 1963 were not available in time to be included in the table, figures shown for the year of review were drawn from other sources and are subject to revision.

PRODUCTION

Production of most major metals and mineral commodities, with the important exception of phosphate rock, was somewhat greater in 1963 than in 1962. However, the internal demand for crude oil, some refinery products, coking coal, fertilizer materials, sulfur, copper, zinc, and a few lesser commodities increased at a greater rate than domestic production, and larger quantities of these materials had to be imported.

[1] Includes export data on some commodities for which production data are not available and on commodities for which export data are more representative than incomplete data on production.
[2] In addition to commodities tabulated, Brazil produces bentonite, china and refractory clays, glass sand, ilmenite, kyanite, limestone, pyrite, ocher, thorium oxide and nitrate, tungsten metal, uranium oxide, and vermiculite, as well as clay, sand, gravel, and stone for construction purposes, but data on quantities are not available.
[3] Estimate.
[4] Data not available.
[5] Revised figure supersedes that given in commodity chapter, volume I.
[6] Preliminary figure for State of Bahia only.
[7] Production of columbite and tantalite are not separately reported; total production allocated on basis of export ratio.
[8] Exports.
[9] Reported production for Minas Gerais and Paraná. Perhaps as much as 20 percent of total gold recovered in Brazil is not reported statistically.
[10] Excludes production by Comissão Nacional de Energia Nuclear (CNEN).
[11] Represents roughly equivalent quantities of Brazilian monazite, export of which is prohibited.
[12] Most of production shown is presumed to be held as stocks as exports are restricted.
[13] Includes anthophyllite, chrysotile, and tremolite fiber. Data shown are estimates, as ore rather than fiber is reported as production for some mines.
[14] Data for one mine only. Total annual production probably is less than 1,500 tons.
[15] Includes rough and cut (but unset) stones except diamonds and rough agate.
[16] Production of marketable apatite and phosphate rock is not reported separately; however, relative quantities produced are indicated by concentrates sold under Government subsidy, as follows: Apatite: 1959—45,297 tons, 1960—68,674 tons, 1961—95,002 tons, 1962—100,264 tons. Phosphate rock: 1959—170,566 tons, 1960—171,063 tons, 1961—116,753 tons, 1962—83,980 tons.
[17] Total merchantable coal averages approximately 60 percent of total mine-run product.

TRADE

Foreign trade in metal and mineral commodities is an important aspect of the Brazilian economy, accounting for 27.8 percent of all imports and 9.4 percent of all exports in 1962. A rapid rate of industrial expansion in recent years has been sustained by importation of large quantities of fuels and lubricants, metals, machinery, and other manufactured items without a commensurate increase in production of exportable goods. As a result, the balance of trade has been unfavorable each year since 1956. Were it not for dependence on for-

Digitized by Google

eign sources for petroleum and some of its derivatives, the trade deficit in the other items would be more than offset by the favorable balances in agricultural products and in ores and minerals. Another facet of the trade deficit is the insignificant market that exists for Brazilian goods in Venezuela, Saudi Arabia, and Kuwait, the principal sources of petroleum imports.

Iron and manganese ores are by far the principal nonagricultural commodities exported, and their sales abroad constitute an important source of foreign exchange. Paradoxically, oil-deficient Brazil presently cannot utilize all the high-paraffin crude it produces, and the surplus is exported. Exports of other ores and minerals are relatively minor compared to the three major commodities, but include such scarce materials as beryl, columbium-tantalum ores, mica, and quartz crystal.

Iron ore exports increased 7.4 percent to 8,217,155 tons in 1963, but the income derived increased only about 1.2 percent because average value of the ore sold was somewhat lower than in 1962. Brazil hopes to sell about 15 million tons of iron ores abroad in 1965 and to double this target by 1970. Manganese ore exports amounted to 840,709 tons in 1963, making a notable recovery from the 1962 slump but still below the record attained in 1961.

Metal and mineral imports during 1963 increased over 1962 levels for all major commodities, including fuels, lubricants, steel semimanufactures, aluminum, copper, and fertilizer materials.

The United States is the principal trading partner of Brazil. Exports to the United States represented 42.7 percent of the total value of goods exported during the period 1958–62 and included about half of the mineral sales. Imports from the United States during the same period accounted for 33.1 percent of the total value of goods imported and included a little less than 20 percent of all metal and mineral purchases. In comparison, western European countries as a group received 36.4 percent of exports and supplied 32.6 percent of imports, with West Germany leading in both categories.

Petroleum products:				
Fuel oil do	75	77	Mainly to United States	1,084,607
Other	12	7	Bolivia 4; Paraguay 3	2,717
Total value, mineral fuels				7,431,723
Total:				
Value of metal and mineral exports.				114,098,940
Value of all exports, f.o.b				1,214,185,488
Metals and minerals percent share in total exports.				9.40

[1] Not reported. May be included in unspecified compounds.
[2] Estimated equivalent on a 60-percent WO_3 basis: 1961, 1050 metric tons; 1962, 750 tons.
[3] Includes material not identified by commodity in foreign trade publications and commodities not listed separately in this table.
[4] Data not available.
[5] Includes emery and pumice. Excludes industrial diamonds.
[6] Includes rough and cut (but unset) stones except diamonds and rough agate.
[7] Probably represents rejected material suitable for tumbling and mineral suites.

The U.S. share of the Brazilian market for metals and minerals is gradually being reduced by stiffer competition from other countries and by increasing use of barter arrangements by Brazil to expand its export markets with other countries. The recently organized Latin American Free Trade Area (LAFTA) also is beginning to influence trade patterns. For example, imports of copper ingot, pig, and cake from LAFTA countries have increased markedly, mainly at the expense of U.S. exporters. The share of imports from LAFTA countries jumped from 5.3 percent in 1961 to 58.5 percent in 1962, whereas the U.S. share dropped from 53.6 percent to 12.6 percent. Also, LAFTA country shares of other crude metal imports rose from 17.4 to 88.5 percent for lead, from 10.7 to 58.8 for zinc, and from 20.9 to 81.2 for silver at the expense of both United States and European exporters. The changed trade pattern for these metals, and perhaps for other commodities as well, apparently has resulted from the more attractive cruzeiro transactions offered by importers in the LAFTA countries, who do not have to meet the compulsory prior deposit requirements or to pay the tariffs (on copper and lead) imposed on imports of non-LAFTA origin.

COMMODITY REVIEW

METALS

Aluminum.—The combined output of the two aluminum reduction plants in Brazil provides only about half of the relatively modest requirements for primary aluminum. Official figures for aluminum-ingot output shown in the production table apparently include ingot derived from both primary and secondary sources; however, an

Digitized by Google

aluminum-market study released by the National Economic Development Bank (BNDE) in 1963 indicates production from primary sources was 15,187 tons in 1959; 16,573 tons in 1960; 18,467 tons in 1961; and an estimated 21,700 tons in 1962. The difference between BNDE and official figures for 1959–61 suggests that scrap metal was the source for about 10 percent of the ingot output.

Growth in production has not lowered import tonnages, because consumption increases have averaged more than 10 percent annually. Despite the need to import crude and processed metal to balance out industrial requirements, the domestic industry continued to enjoy high-protective tariffs on aluminum—50 percent ad valorem on crude and semifabricated metal, 50 to 80 percent on fabricated products, and 100 percent on household articles. However, consumers of crude metal pay only 10 percent ad valorem on imports, providing 30 percent or more of their requirements have been obtained from domestic producers. This exemption applies also if domestic sources cannot provide the 30 percent.

Brazil has ample reserves of bauxite in the States of Minas Gerais and São Paulo but a shortage of electric power continued to inhibit expansion of existing aluminum reduction facilities and has delayed plans to construct new plants. The large Furnas and Três Marias hydroelectric projects in Minas Gerais should make more power available for aluminum reduction in the near future. Anticipating this probability, state entities proposed the erection of a new 25,000-ton plant at Santa Luzia which would utilize power supplied by the state-controlled power company, CEMIG, and bauxite from recently discovered deposits near Serro; reserve estimates for these deposits range from 10 to 100 million tons. Until this or some other new plant can be implemented, the country must rely on increased production at the two operating plants to contain the volume of aluminum imports as consumption increases.

Cia. Brasileira de Alumínio nearly completed an expansion program at its completely integrated plant near Sorocaba, São Paulo. The new facilities should be operative early in 1964, and will increase the alumina capacity of the plant from 25,000 to 45,000 tons and the ingot capacity from 11,000 to 21,000 tons. A new 35,000 kilowatt company-owned hydroelectric plant will supplement the power now being supplied by a 30,000-kilowatt plant. Bauxite for the alumina plant is shipped by rail from company deposits at Poços de Caldas, Minas Gerais. Reserves of these and other deposits in the area total more than 40 million tons.

The other primary aluminum plant in Brazil is at Saramenha, near Ouro Preto, Minas Gerais and is operated by Alumínio Minas Gerais, S.A., a subsidiary of Alumínio do Brasil, S.A., which in turn is affiliated with Aluminium, Ltd., of Canada. Ingot produced at Saramenha is shipped to São Paulo for fabrication at the plant of the parent company. Installed capacity in 1963 was for 28,000 tons of alumia and 14,000 of ingot. Alumina capacity is to be increased to 40,000 tons and ingot capacity to 20,000 tons, but the additional facilities may not be fully operative until 1966. The company generates part of its power supply at five small hydroelectric plants with a total installed capacity of 29,500 kilowatts and purchases the remainder

Digitized by Google

of about 12,000 kilowatts from CEMIG. Bauxite is mined from nearby company deposits which have reserves of about 1.4 million tons.

Columbium.—Distribuidora e Exportadora de Mineiros e Adubos, S.A., (DEMA) finally obtained approval from the Comissão Nacional de Energia Nuclear (CNEN) to export pyrochlore concentrate produced from the large deposit at Araxá, Minas Gerais. An export license was issued at midyear under an agreement whereby the radioactive equivalent of thorium contained in the concentrate would be returned to Brazil in the form of South African yellowcake, enabling DEMA to export 765 tons of concentrate (53 percent Cb_2O_5) from its 1,600-ton stockpile to the United States late in the year. The modern mining and milling facilities installed by DEMA at Araxá represent an investment of US$2 to 3 million, and the company suspended commercial production until the stockpile could be disposed of. During most of 1962 and 1963, operations were limited mainly to research and development. The company experimented with a thermite process for making thorium-free ferrocolumbium and succeeded in producing about 2.5 tons of the alloy in 1963. The stock of concentrates was rerun through the mill and a new leaching unit to reduce the amounts of contained silica and sulfur. In addition, the mill produced about 25 tons of new concentrate.

Copper.—The supply position in primary copper has been very unfavorable for Brazil, and this situation will become more acute each year as consumption increases. Less than 5 percent of the copper requirements have been derived from domestic ores, making it necessary to expend about US$30 million annually on imports of the refined metal.

Reserves of known deposits containing more than 1 percent copper are rather small, and as yet none of the known lower grade deposits have proved large enough to warrant large-scale recovery operations. The Caraíba deposit in northern Bahia has been drilled to depths of from 100 to 200 meters and is estimated to have a reserve of about 40 million tons of disseminated ore (chalcopyrite) averaging about 0.9 percent copper. Geochemical prospecting in the general area is being conducted jointly by the Departamento Nacional da Producão Mineral, AID, and the University of Bahia. An anomaly was found near Santa Rosa in 1963 that is similar to the one observed at Caraíba. A preliminary appraisal indicates the possible existence of about 30 million tons of ore, but the area will have to be drilled to determine size and grade of the ore body. Explorations are to be continued in the hope of finding enough ore in the region to permit large-scale mining and smelting operations.

Virtually all the primary copper output of the country is mined, smelted, and refined by enterprises controlled by the Pignatari interests of São Paulo. Two small sulfide deposits in Rio Grande do Sul contribute the bulk of the ore and concentrate produced. The concentrate is trucked more than 1,300 kilometers to the Pignatari smelter at Itapeva, São Paulo, where it is reduced with charcoal to black copper. This smelter also treats some oxide ore from the nearby Santa Blandina property and, in recent years, has also treated small quantities of hand-picked (11 to 14 percent copper) Caraíba ore. The smelter product is refined by Laminacão Nacional de Metais at a plant in

Digitized by Google

Utinga, São Paulo, which has both electrolytic and fire refining facilities and also produces copper and copper alloy products and metal powders.

Iron and Steel.—The iron and steel industry, largest in Latin America, continued its rapid expansion during 1963 as new facilities for producing and finishing steel became operational, and other expansion projects neared the completion stage. Actual production, however, was insufficient to satisfy the increasing demand for steel in the country, and imports of basic steel products increased markedly during the year. The Government created the Executive Commission for Importation of Steel Products (CEPLA) to supervise and regulate imports of essential steel products. Cia. Siderúrgica Nacional (CSN), the government-owned company that produces about one-third of the national steel output and sets the pace for the industry, was permitted to raise its prices by an average 40 percent. Commensurate price increases by other companies helped to avoid a financial crisis that was facing the industry in general.

Estimated output of ingot steel during 1963 was 2.812 million tons, of which CSN produced 1.268 million tons. CSN hopes to increase its ingot capacity to 1.5 million tons by 1965. The National Economic Development Bank (BNDE) estimates that national steel capacity will be about 4.68 million tons of ingots and 3.73 million tons of finished products in 1965 but predicts that demand will then exceed production by about 720,000 tons of ingots and 470,000 tons of rolled products. Imports of steel semimanufactures will have to be increased considerably in order to balance the expected shortfall.

Most major and several smaller steel companies were involved in significant expansion activities during 1963. Cia. Siderúrgica Belgo Mineira, the second largest steel producer, neared completion of a program to raise ingot capacity to 500,000 tons per year. The company also has moved its wire and tube mills from the Monlevade works to new sites near Belo Horizonte and Santa Luzia in Minas Gerais.

Usinas Siderúrgica Minas Gerais (USIMINAS), which fired its first blast furnace and initiated pig iron and ingot steel production in October 1962, inaugurated the first units of a rolling mill in June 1963. The mill is designed to produce plates up to 108 inches wide and 75-inch-hot and 61-inch-cold-rolled sheets to supply the naval construction and automobile industries. The steelmaking capacity of the company reportedly will be 600,000 tons per year when the second blast furnace and other facilities begin operation in 1964. Production in 1963 included 217,790 tons of pig iron and 73,417 tons of steel ingots. The USIMINAS plant is near Ipatinga, Minas Gerais, and represents a joint venture in which Brazilian interests, principally BNDE and the State of Minas Gerais, have a share of 60 percent, and Japanese interests have the remaining 40 percent.

Cia. Siderúrgica Mannesmann inaugurated a new blast furnace at its steel works near Belo Horizonte in March. Other new units put into operation include a coke oven, gasometer, a third electric furnace, two LD converters, and an oxygen generator. The additional facilities have increased annual ingot capacity from 146,000 to 350,000 tons.

Digitized by Google

Mannesmann specialize in seamless pipes and tubes made under patents held by its West German parent company.

Cia. Ferro e Aço de Vitoria inaugurated its new rolling mill at Vitoria, Espirito Santo, in October. The mill will produce medium and light finished structural steel at an initial rate of 130,000 tons per year from ingots supplied by USIMINAS until the plant becomes integrated. Additional facilities to permit the annual production of 380,000 tons of ingots and 310,000 tons of structural steel are scheduled for completion in 1967, and further expansion to 2,000,000 tons of ingots and 1,600,000 tons of finished products is projected for 1971–72. BNDE holds a 95 percent interest in this steelworks, and the remainder is divided among private Brazilian and West German investors.

Cia. Siderúrgica Paulista (COSIPA) formally inaugurated its new steel rolling mill at Piaçaguera, São Paulo, in December, thus surmounting at least some of the technical, financial, and administrative difficulties that have delayed the project. The mill began producing hot-rolled sheets and coils from ingots supplied by USIMINAS, and plans called for adding cold-rolled sheets to the line during 1964. Trade sources estimate probable output for 1964 at between 250,000 and 400,000 tons. When completed, the COSIPA works will be fully integrated with an annual capacity of 500,000 tons of ingots and 400,000 tons of rolled sheet products. Shares in COSIPA are distributed as follows: 58.2 percent with BNDE, 23.3 percent with the State of São Paulo, 2.7 percent with state-controlled entities, 6.7 percent with the National Treasury, and 9.1 percent with private investors.

Iron Ore.—Iron ore was the principal mineral commodity produced in Brazil and by far the most important mineral exported. Annual output has more than doubled since 1958, and exceeded 10 million tons in the last 3 years. About one-fourth of the ore produced is consumed by the domestic iron and steel industry, and the remainder is exported. The bulk of iron ore output comes from extensive hematite deposits in the Quadrilátero Ferrífero of Minas Gerais, although deposits in Paraná, Mato Grosso, Bahia, and São Paulo supply relatively small quantities that amount to only about 1 percent or less of the total. The total iron ore reserve in the country has been estimated as approximately 42 billion tons, but a large fraction of this figure represents material that has little economic significance at present because of its low grade, physical nature, or remote location. Nonetheless, the indicated and inferred reserves of deposits of high-grade hematite ores (plus 66 percent iron) in Minas Gerais alone, which total more than 3,300 million tons, are among the largest in the world and are more than ample to supply the foreseeable market for Brazilian ores.

Iron ore production is dominated by two government-controlled companies, Cia. Vale do Rio Doce, S.A. (CVRD), and Cia. Siderúrgica Nacional (CSN). CSN mines ore from its own deposits in the Congonhas District of Minas Gerais and purchases some ore from other producers to feed its steel mill at Volta Redonda, Rio de Janeiro. CVRD produces iron ore for export from five major mines it owns or leases in the Itabira District of Minas Gerais. This company also owns and operates the only railroad connecting this district with the port facilities at Vitoria, Espirito Santo. In 1962, CVRD accounted

Digitized by Google

for 52 percent of total iron ore output and 80 percent of its exports, whereas CSN produced 12 percent of the output.

CVRD is engaged in an extensive program of improving its mine, railroad, and port facilities to service its own export commitments and also to provide transport services for other companies that must export from Vitoria. The company is constructing a new ore terminal 10 kilometers from Vitoria with facilities to permit the export of about 15 million tons of ore per year. When completed in 1966, this port will accommodate ships of 100,000 deadweight-tons. The installation has been designed to car-dump cuts of 50 cars, without uncoupling, into a conveyor system that will stockpile, reclaim, and shipload ore at a rate of 6,000 tons per hour. A screening plant is included in the system to classify the ore according to size specifications of the customer. The new port will also include facilities to tranship coal destined for steel mills in the Rio Doce Valley.

As of 1963, the export commitments of CVRD included short- and long-term contracts for the delivery of approximately 100 million tons of ore to customers in 13 countries, principally Japan and West Germany. To assure fulfillment of these commitments, the company also has negotiated with S.A. Mineracão da Trinidade (a subsidiary of Cia. Belgo Mineira), Mineracão de Ferro e Carvão, and Mineracão Serro da Moeda to supply export ores from their mines under an agreement whereby these companies will be able to utilize CVRD transport facilities to export equal amounts of ore for their own account, providing the profits are reinvested in the iron and steel industry.

Construction of another new port for iron-ore export presumably was started in 1963 by Cia. Siderúrgica da Guanabara (COSIGUA) at Santa Cruz, Guanabara. This port will have a capacity of 10 million tons per year and will provide an export outlet for some of the ores produced in the western part of the Quadrilátero Ferrífero. A steel mill also is to be built at Santa Cruz by COSIGUA.

Manganese.—Manganese ore is one of the most important mineral resources in Brazil and the second largest mineral export commodity. Reserves of known deposits may total from 100 to 150 million tons; about two-thirds occur in deposits in the Urucum District of Mata Grosso and most of the remainder in deposits in the Territory of Amapá and the states of Minas Gerais and Bahia. The bulk of the ore produced in the country since 1956, as well as the bulk of exports, has come from the Serra do Navio deposits in Amapá, which are mined by Indústria e Comércio de Minério, S.A. (ICOMI), under a 50-year concession from the Territory. The ICOMI operation, in which the Bethlehem Steel Co. has a 49 percent interest, is one of the best planned and executed large mining enterprises in Brazil. In addition to the modern mining, crushing, washing, and auxiliary facilities, the company operates a 193-kilometer, standard-gauge railroad from the mine to Porto Santana, where it has docking and loading facilities for oceangoing vessels. According to a company official, 827,200 tons of washed ore (plus 48 percent manganese) was produced from 1,083,000 of crude ore in 1963, and shipments from the port totalled 816,500 tons for the year. Most, if not all, of the ore shipped was destined for the United States.

758-002—65——16

Digitized by Google

Minas Gerais is the second largest manganese-producing state. Most of its output is sold to domestic consumers as exports have been curtailed in recent years to guarantee an adequate, low-cost supply for the local market. Data on 1963 production are not available, but output for 1961 and 1962 was 181,491 and 164,618 tons, respectively. The largest manganese producer in the state has been the United States Steel Corp. subsidiary, Cia. Meridional de Mineracão (MERIDIONAL), which operates the Morro da Mina mine near Conselheiro Lafaiete, but the large manganese deposits discovered relatively recently by Cia. Belgo Mineira near Alegria promise to figure prominently in future output.

The manganese ores mined in Mato Grosso and Bahia are destined primarily for export. Sociedade Brasileira de Mineracão, Ltda. (SOBRAMIL), owned by the Chamma brothers, is the sole producer in Mato Grosso. This firm receives financial and technical assistance from MERIDIONAL in return for credit on ore purchases for export markets previously supplied by Morro da Mina ore. Ore containing 45 to 46 percent manganese is barged down the Paraguay River to Nueva Palmyra, Uruguay, where it is transferred to oceangoing vessels and shipped to Santos or Rio de Janeiro for export. Shipments in 1963 totaled 62,658 tons, as compared with 21,825 and 23,216 tons in 1961 and 1962 when low water precluded normal barging operations. Exports by three producers in Bahia decreased from 28,735 tons in 1962 to 10,500 tons in 1963.

Nickel.—National consumption of nickel was reported as approximately 1,800 metric tons for 1962, more than double the average of the 5 previous years; however, consumption may have decreased slightly during 1963. Brazil has large reserves of garnierite ores, but it lacked adequate reduction facilities prior to 1963, and from 90 to 95 percent of the annual nickel requirements of the country were imported as metal, semimanufactures and chemicals—valued at almost US$2.71 million in 1962. Inauguration of a second ferronickel plant in the latter part of 1962 provided Brazil with the capacity to produce more than enough ferronickel to supply internal demand for nickel in that form and a part of the surplus was exported in 1963.

In 1963, Morro do Níquel, S.A., produced 937.6 metric tons of nickel in the form of ferronickel at its new plant near Passos, Minas Gerais. The company is planning to install facilities to further reduce some of its alloy output to pure metal and to nickel salts. Cia. Níquel do Brasil has announced plans to triple production of ferronickel at its plant at Liberdade, Minas Gerais, and also is considering production of nickel and nickel-chrome steels. Annual alloy output by this firm averaged 318 metric tons for the period 1958–62.

Pressures by the State of Goiás to activate mining of the large deposits of garnierite near Niquelândria appeared to gain ground in 1963 when the principal concessionaire, Cia. Níquel Toncantins, agreed to form a mining corporation in which its parent company, Grupo Votorantim, S.A., will retain a 60 percent interest, and the remaining 40 percent will be held by state-controlled Metais Goiás, S.A. (METACO). The new corporation, Nibrasa-Niqueis do Brasil, S.A., proposes eventual production of 5,000 tons of ferronickel and the possible recovery of several hundred tons of cobalt as well as some copper.

Tin.—Rich alluvial tin deposits in the Territory of Rondônia, adjacent to Bolivia, have been worked at gradually increasing rates since 1959 leading to widespread speculation on the possibility of Brazil becoming a major low cost tin producer. The occurrence of tin in the district was first reported by a geologist, Dr. Donald F. Campbell, in 1950, but the potential of the area still is obscure, and it may be several years before the known deposits can be properly evaluated. Available information, which is somewhat meager, indicates that several large areas of relatively rich placer ground have been discovered, and at least eight small-scale recovery operations were active in 1963; three of these employed partially mechanized sluicing methods. Transportation to the coast is costly, and actual production thus far has been relatively small.

The tin occurs as fine to very coarse (up to 30 centimeters in diameter) fragments and crystals of cassiterite in the alluvial material overlying basement rocks which are mainly Precambrian grantic rocks. The known deposits apparently are rather rich as ground containing less than 5 kilograms of cassiterite per cubic meter is being bypassed or discarded, and pay streaks on the bedrock reportedly yield as much as 80 kilograms per cubic meter although the average probably is only 10 to 30 kilograms. Zircon and topaz are reported to be abundant in some of the sands and may become valuable byproducts when large-scale mining methods become operative. Ilmenite and columbite-tantalite also have been reported. Insofar as is known, the primary source of the cassiterite has not been found in any of the areas, but tin-bearing cobbles in the alluvium indicate a derivation from greisen-type deposits formed by pneumatolytic mineralization of the granites or gneisses.

Elsewhere Brazilian tin is produced from widely scattered localities in Minas Gerais, Goiás, Amapá, Paraíba, and Rio Grande do Sul. The steadiest production in recent years has been from the São João del Rei district in Minas Gerais. The modern, well-equipped tin smelter of Cia. Estanífera do Brasil at Volta Redonda produces refined tin from Brazilian and imported ores. There are several other small tin smelters in operation.

NONMETALS

Cement.—Brazil is by far the leading cement producer in Latin America and in 1963 ranked 15th among all cement-producing nations with an output amounting to 1.4 percent of the world supply. Virtually all the cement requirements of the country have been supplied by domestic production since 1956. The small quantities imported from Uruguay in 1962 and 1963 to alleviate a shortage in the State of Rio Grande do Sul were more than balanced by exports to Bolivia and Paraguay.

In 1963 the progressive and well-organized cement industry comprised 29 operating plants with a total installed annual capacity of 6,155,000 tons. All the plants have rotary kilns of foreign manufacture, and all but five use the wet process. The industry is controlled and financed largely by nationals. However, one U.S. firm, the Lone Star Cement Corp., controls two plants representing about 11 per-

Digitized by Google

cent of total capacity, and five other countries have minor investments in cement.

The average level of operation during the year attained only 84 percent of capacity, and output rose only 4 percent as compared with gains of 5.5 percent in 1962 and 22.7 percent in 1961. A part of the increase represents partial recovery of output lost by the Perus plant during a 102-day strike in 1962. The Votorantim plant at Sorocaba, São Paulo, the largest in Brazil, increased output considerably due to expansion completed in 1962; however, this plant and some other plants probably curtailed planned production because of a general slowdown in the construction industry.

Most expansion plans of the industry were deferred in 1963, but the Caué plant at Pedro Leopoldo, Minas Gerais, put a second Allis-Chalmers kiln into operation in midyear, increasing capacity from 110,000 to 243,000 tons per year. Also, Itabira Agro-Industrial, S.A., was reported to be remodeling the old Barbará plant in Espirito Santo and expects to become the second producer in the country of white and special cements, having a capacity of 50,000 tons. Known expansion plans include the construction of 7 new plants with a total capacity of 723,000 tons and capacity expansion of existing plants by about 200,000 tons. However, these projects will not increase total capacity enough to provide the cement requirements predicted for 1965, and imports may be necessary to supply the deficit.

Phosphate Rock.—Output of phosphate rock in Pernambuco declined again in 1963 as the 250,000-ton beneficiation plant of Fosforita Olinda, S.A., near Recife operated at less than one-fifth capacity. The company produced only about 35,000 tons from January through September as compared to the peak output of 160,471 tons in 1960. The principal market for Pernambuco phosphate is in the south-central part of the country, but maritime freight rates to southern ports have become so prohibitive that Fosforita Olinda cannot compete with the imported product even though it receives the subsidy paid for domestically produced fertilizers. According to Banas Informa, the cost of shipping fertilizer from Recife to Santos almost doubled between January 1962 and the end of 1963. The company also is faced with depletion of reserves of ore amenable to open-pit, dragline-mining methods, and recovery of other ores probably will be more costly.

MINERAL FUELS

Petroleum.—The trend toward a completely state-dominated petroleum industry was further implemented by two measures adopted in December 1963. The National Petroleum Council Resolution No. 8–63, published December 17 in Diário Oficial, authorized Petróleo Brasileiro, S.A. (PETROBRÁS), the national petroleum entity, to distribute petroleum products throughout the country. PETROBRÁS previously had distributed such products in areas surrounding its refineries and had supplied government agencies but did not compete generally with private distributing firms. Presumably, additional distributing activities will be conducted through its subsidiary, DISBRAS, which was created in 1959. Decree No. 53,337 published

Digitized by Google

December 24, gave PETROBRÁS the exclusive right to import crude-oil and petroleum derivates, and private refineries now must import their crude-oil requirements through PETROBRÁS. Control of imports is expected to facilitate negotiations for exchanging iron ore and other export products for crude oil and to permit greater use of the Brazilian tanker fleet to transport goods. It is further anticipated that bulk-buying should result in a saving of foreign exchange. Import control also might facilitate eventual displacement of private distributing enterprises. At yearend it appeared almost inevitable, if not iminent, that PETROBRÁS would be authorized to take over control of all private refineries and thus make its petroleum monopoly virtually complete.

The oil industry registered modest gains in output of crude oil and refinery products during 1963, despite continued troubles involving the administrative, financial, and political activities of PETROBRÁS. Crude-oil production, all from fields in Bahia, attained a new peak that was 6.9 percent higher than the previous year but only 2.6 percent more than that of 1961. The increase is attributed partly to additional producing wells and partly to use of water injection in secondary recovery operations. PETROBRÁS drilled 146 development and 76 exploratory wells during the year, and in October, its Director confirmed a new discovery by a 100-barrel-per-day well at Carmópolis, Sergipe. Also announced were plans to supplement its 61 drilling rigs by purchase of from 9 to 14 new rigs from Rumania.

Two of the three PETROBRÁS refineries and most of the six private refineries operated at near or above nominal capacity during the year, and total throughput averaged almost 305 million barrels daily, about 7 percent greater than in 1962. Imported crude oils constituted about 71 percent of total refinery feedstock. Output of refinery products increased 7.7 percent from the previous year, largely due to increases in production of diesel and fuel oils. Output of liquefied gases and asphalt also increased notably, and that of lubricating oils almost quadrupled as the Landulfo Alves refinery began producing lubricants. Output of kerosine declined, however, and it was announced that the Duque de Caxias refinery would cut back production of diesel oil in order to increase that of kerosine and gasoline.

PETROBRÁS let a contract to a consortium of Italy's Ente Nazionali Idrocarbui (ENI) and the Brazilian firm of Engebras for the construction of the Gabriel Passos refinery at Belo Horizonte, Minas Gerais, and the Alberto Pasqualini refinery at Canoas, Rio Grande do Sul. Capacity of each installation is to be 45,000 barrels per day, and completion is scheduled for 1966. Work is underway on a 362-kilometer, 18-inch pipeline from the Almirante Tamandaré terminal in Guanabara Bay to the Gabriel Passos refinery site, and completion is programmed for 1964. Until the new refinery is completed, this pipeline is to be used to supply the Belo Horizonte area with petroleum products from the Duque de Caxias refinery. A 116-kilometer pipeline will connect the Canoas refinery with an ocean terminal at Tramandaí.

The Mineral Industry of British Guiana

By Garn A. Rynearson[1]

THE NOTABLY progressive growth of the mineral industry in recent years was sharply arrested in 1963 by intensified political and racial disturbances. The most serious of these was a 79-day general strike during the second quarter of the year which severely disrupted operations in the largest industry in the country, mining and processing bauxite. Largely because of this strike, output of bauxite in 1963 decreased almost 14 percent from the record production level attained in 1962. Although the total quantity of dried bauxite produced for export (metallurgical and chemical grades) by the two bauxite companies was 35 percent less than in 1962, the Demerara Bauxite Co. was able to minimize the effect of the strike on its operations by concentrating on the production of higher value calcined bauxite (abrasive and refractory grades) and alumina. It even managed to increase its alumina output by a little more than 1 percent. Reynolds Metals Co., which produces only dried bauxite, was affected more seriously, as its ore transport system could not compensate for time lost, and output was only 63 percent of that of the previous year. As a result, one of the major customers of the company had to obtain a part of its supply for the year from Surinam.

Bauxite and alumina are by far the most important mineral commodities produced in British Guiana. The combined export value of these products generally represents between 75 and 85 percent of the value of all reported mineral production and between 25 and 30 percent of the value of all exported goods. Bauxite output was a little less than 8 percent of the world total in 1963 and nearly 9 percent in 1962. British Guiana was the leading world producer of bauxite in 1940 and 1946, held second place from 1947 to 1954, and has ranked fourth since 1959. Total output from 1917 through 1963 amounted to 45 million metric tons, representing 11.6 percent of the world supply during that period. Only Surinam and Jamaica have produced more than that amount. All of the bauxite produced has been destined for export either as raw or as calcined bauxite or, since 1960, as alumina. The country has no facilities for making aluminum metal or aluminum chemicals other than alumina.

British Guiana is a significant producer of manganese ore and diamonds, ranking either second or third among Western Hemisphere nations in the output of each of these commodities in recent years. The only other minerals regularly produced are gold and sand, gravel, and crushed stone for construction; however, the amounts produced are relatively modest. Manganese ore and both gem and industrial

[1] Physical scientist, Division of International Activities.

Digitized by Google

diamonds are produced for export, but the amount of gold recovered in recent years has barely sufficed the local jewelry industry. British Guiana is a potential producer of sands suitable for glass, of kaolin, and perhaps of petroleum and gas (from possible offshore deposits). Shell accumulations on the beaches are the only known domestic source of lime and some probably have been worked on a small scale. A variety of other minerals has been found in the country but deposits of commercial significance were not known as of 1963. Much of the country is nearly inaccessible and is difficult to prospect. It is hoped, however, that UN-sponsored aeromagnetic surveys, begun in 1962, may lead to discovery of new mineral deposits of economic importance.

The colony includes an area of 83,000 square miles that can be divided roughly into three main regions: (1) A low-lying coastal region varying in width up to 30 miles that constitutes the agricultural area; (2) a higher inland region about 100 miles wide that is almost entirely forested and within which most of the important mineral deposits occur; and (3) a generally high plateau and mountain region with extensive savannahs that borders Brazil and Venezuela. About 90 percent of an estimated population of 630,000 people live in the coastal region. Agriculture employs about 35 percent and mining about 6 percent of the colony's labor force, which was estimated to number about 195,800 in 1962. Approximately half of 12,000 persons engaged in mining activities in 1961 were individual prospectors or pork-knockers searching for diamonds; about 5,000 were employed by the bauxite companies; and 650 were employed by a manganese mining company.

British Guiana is a crown colony with a constitution that provides for full home rule except that Great Britain appoints the Governor and retains control over matters of defense and external affairs other than trade. It is generally expected that independence within the British Commonwealth of Nations will be granted within a few years. The country has a Lands and Mines Department in the Ministry of Natural Resources and a Geological Survey Department in the Ministry of Trade and Industry.

British Guiana economy is based largely on production and export of agricultural and mineral products. Estimated distribution of the gross national product indicated that agriculture, forestry, and fishing contribute 26 percent; mining, 13 percent; and manufacturing, 14 percent. The latter category may include manufacture of alumina as other manufacturing in the colony is rather limited. Sugar is most important in the economy in that its production provides a livelihood for the largest segment of the population, and its export accounts for about 40 percent of foreign exchange earnings. Although production of mineral products supports a relatively small number of people, the total export value of such products normally accounts for about one-third the value of all exports. The mineral industry also provides an appreciable source of Government revenue through taxes and other income such as leases, licenses, and royalties. In 1961, for example, nontax revenue from mining and quarrying amounted to about BWI$840,000.

SOURCE MATERIAL

General background material and information pertaining specifically to the mineral industry are based largely on despatches from the U.S. Consulate General in Georgetown and on official publications of several agencies of the Government of British Guiana. The latter sources include the following:

1. Annual report—British Guiana, published by the Government for the years 1959 to 1961.
2. Annual reports of the Lands and Mines Department, 1959 to 1961.
3. Annual reports of the Geological Survey Department, 1959 to 1961.
4. Monthly and annual publications of the Department of Customs and Excises, 1960 to 1962.

Additional information on specific mineral commodities was derived from:

1. Stockley, G. M. The Geology of British Guiana and the Development of Its Mineral Resources, British Guiana Geological Survey Department Bulletin 25, 1955.
2. Bishopp, D. W. The Bauxite Resources of British Guiana and Their Development, British Guiana Geological Survey Department Bulletin 26, 1954.
3. Bracewell, Smith. Bauxite, Alumina, and Aluminium, Overseas Geological Surveys, 1960, pp. 104–110.

Statistical data on mineral production are those reported by the Consulate General and include figures obtained from both official and company sources.

The compilation and publication of official trade data is behind schedule due to the general strike during 1963, and 1961 is the latest year for which complete data have been published; incomplete data have been published for January through November of 1962. Therefore, trade data given for 1962 and 1963 are preliminary estimates and are subject to revision.

The unit of currency in British Guiana is the British West Indies dollar (BWI$). Values given in U.S. dollars have been converted at the rate of BWI$1.00=US$0.58.

PRODUCTION

The total value of mineral commodities produced in British Guiana during 1963 amounted to approximately US$33.2 million, compared with US$37.9 million in 1962 and US$29.9 million in 1961. These figures exclude clay, sand, and natural gravel utilized in roads and dikes and other construction projects. Total value given for 1961 was derived from f.o.b. export values of bauxite, alumina, and manganese ore; the values reported by the Commissioner of Lands and Mines for diamonds and gold; and an estimated value for quarried stone. Total values given for 1962 and 1963 are estimates, based on average export values for 11 months in 1962 except for gold and stone whose values were estimated more or less arbitrarily. Decreased bauxite production in 1963 was a result of the long general strike but the drastic reduction in manganese ore output, which amounted to little more than half

Digitized by Google

that of 1962, stemmed more from difficulties encountered in marketing the relatively low grade ore (42 percent Mn) than from adverse effects of the strike.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Aluminum:					
Bauxite	1,701,290	2,510,853	2,411,712	[2] 2,762,637	2,379,883
Alumina, exports			122,090	[3] 211,286	[3] 225,708
Gold, troy ounces	3,448	2,364	1,702	1,903	2,847
Manganese ore and concentrate		[4] 124,696	196,136	275,454	142,728
Nonmetals:					
Diamonds [5], carats	62,328	101,004	112,680	100,145	99,748
Total number of stones	430,446	710,671	1,024,033	728,150	766,034
Stone, granite, crushed or broken	68,370	86,912	57,664	35,507	11,892

[1] In addition to commodities tabulated, British Guiana produces clay, sand, gravel, and crushed or broken stone (other than granite) for construction purposes, but data on quantities are not available.
[2] Data from Statistical Summary of the Mineral Industry, 1957-62. Overseas Geological Surveys.
[3] Reported as sales for export.
[4] Revised figure supersedes that given in commodity chapter, volume 1.
[5] Includes both gem and industrial diamonds. Approximately 60 percent of production is estimated to be of gem quality.

TRADE

In 1961, the latest year for which complete trade data were available, the total value of all goods exported from British Guiana was BWI$148 million, and the value of imports was BWI$146.5 million. Preliminary unpublished data from official sources indicated that exports increased substantially in 1962 to BWI$164.5 million. An official estimate was not available for 1963 but the U.S. Consulate General at Georgetown estimated that exports during the year amounted to roughly BWI$166 million, the increase being attributed to higher sugar prices, which more than offset the decrease in bauxite exports. Preliminary unpublished import data indicated an increase in imports to BWI$156.4 million in 1962 and then a sharp decline to BWI$108.4 million in 1963. The decline was attributed to reduced imports of consumer goods, as a result of the general strike, and of capital goods, as a result of lack of investor confidence, as well as failure of the Government to obtain sufficient foreign aid funds to maintain momentum in its development program.

Sugar and sugar products constitute the most valuable export commodity group—followed by bauxite and alumina, rice, manganese ore, and diamond. As a percentage of 1961 exports, sugar represented 40.6 percent, bauxite and alumina 27.6 percent, rice 15.4 percent, and manganese ore and diamonds about 3.5 percent each. These proportions apply roughly to exports for 1962 and 1963, the variation for a given commodity being no more than 5 or 10 percent.

Principal customers during 1961 and 1962 were Canada (bauxite, alumina, sugar), United Kingdom (sugar, diamonds), United States (sugar, bauxite, manganese ore, diamonds), and Trinidad (rice) in the order listed.

Based as it is on agriculture and mining, British Guianan economy depends largely on imports to provide its needs for most capital goods and many types of consumer goods. Virtually all requirements for

Digitized by Google

metals and fuels as well as many of the raw materials needed for use in agriculture and construction are imported. Mineral fuels and lubricants represent about half of all imports of metals and minerals. Fertilizer materials, iron and steel semimanufactures, and cement also are imported in relatively large amounts.

COMMODITY REVIEW

METALS

Aluminum.—The most important bauxite deposits occur within a zone about 10 miles wide and 110 miles long, which extends south-southeast from an area northwest of Bartica on the lower Essequibo River to an area between the Berbice and Courantyne Rivers about 25 miles from the border with Surinam. This zone coincides roughly with a line demarking the eastern outcrop limit of the crystalline basement rocks. Bauxite also has been found along the northwestern ex-

Digitized by Google

tension of this zone to the Venezuela border but none of the known deposits in this region are large enough to be of commercial significance. Laterites and ferruginous bauxite cover hills and ridges of igneous rocks west and southwest of the zone of commercial deposits and also cover large areas in the Pakaraima Mountains on the central-west edge of the colony; however, none of these deposits are of economic importance at present.

The commercially important bauxite deposits are grouped in four main areas roughly 10 miles in diameter and separated by from 15 to 30 miles of comparatively barren territory. The northernmost group, along and near the Essequibo River in the vicinity of Bartica, has not been exploited. The most important group comprises the numerous large and small deposits on both sides of the Demerara River in the vicinity of Mackenzie which is about 60 miles south of the capital city of Georgetown. These and a smaller group of deposits near Ituni about 35 miles south are worked by the Demerara Bauxite Co., Ltd. (DEMBA). The Reynolds Metals Co. works a fourth group in the vicinity of Kwakwani on the east side of the Berbice River.

DEMBA, a subsidiary of the Aluminum Company of Canada, Ltd., made the first shipments of British Guiana bauxite in 1917 and has since been the principal producer. The Plantation Bauxite Co. worked deposits near Christianburg in the Mackenzie area from 1953 to 1957 when it sold its mining rights to DEMBA, and the Berbice Co., Ltd., worked the Kwakwani deposits from 1943 to 1953 when Reynolds took over operations in that area. Other companies have explored for bauxite but none has reached the production stage. Notable activities in recent years have been the intermittent exploration of the Bartica and other areas by Harvey Aluminum of America and an investigation of laterites in the central part of the colony by Petromina (British Guiana), Ltd. Harvey gave legal notice of its withdrawal from British Guiana in 1963.

The DEMBA ore processing and shipping facilities are at Mackenzie, on the Demerara River near the upper limit of navigation for small seagoing vessels. Ore ships can load only about 8,000 tons at Mackenzie, and the larger carriers complete their cargo at a transfer station at Chaguaramas in Trinidad. Ores from deposits on the east side of the river are moved to the processing plant over a system of company railroads. Ores from deposits near Christianburg on the other side of the river have been barged across in the past but the company has announced it will construct a combined rail and highway bridge across the river to make resumption of mining in that area economical.

In general, the ore bodies in the Mackenzie and Ituni areas are dome-shaped lenses from 10 to 40 feet thick and sloping away steeply at their margins. They are underlain by kaolinic clays that have been developed, or perhaps deposited, on the irregular surface of weathered basement rocks. A sequence of sands and clays known as the White Sands series overlies most of the bauxite. The thickness of overburden varies widely, partly because of the east to northeast dip of the bauxitic zone and a thickening of the White Sands series in those directions and partly because of variations in the topography. Mostly, the overburden is less than 50 feet thick but some important ore bodies are overlain in places by more than 150 feet of sands and

Digitized by Google

clays, and their removal constitutes a major mining problem. Waste stripping is accomplished with such equipment as hydraulic monitors, power shovels, and both small and large draglines, including one with a 10-cubic-yard bucket and a 235-foot boom. To cope with the increased overburden, the company acquired a bucket wheel excavator capable of removing 600 cubic yards per hour and excavating to a depth of 122 feet. This machine has been in operation since early 1962.

At Mackenzie the bauxite is crushed, washed, and screened to remove some of the sand and clay impurities and then is dried or calcined. Part of the dried bauxite has been converted to alumina in the 220,000-ton alumina plant of the company since March 1961, and the remainder has been exported. A relatively small part of that exported was chemical grade. Annual output of calcined bauxite averaged approximately 370,000 tons from 1961 to 1963, roughly 50 to 60 percent was dead burned to a product destined for refractory uses, and the remainder was partly calcined to abrasive grade.

For some years DEMBA has been experimenting with a special process for making synthetic mullite. A few hundred tons of this material has been made in a small pilot plant and has been distributed abroad for market research purposes. A favorable response to the product has encouraged the company to proceed with plans to construct a full-scale plant with a maximum capacity of 50,000 tons per year. Completion of the new plant is scheduled for the latter part of 1964.

The bauxite deposits in the Kwakwani area are similar to those worked by DEMBA, but the scope of the Reynolds operation is much smaller, largely because of natural limitations which tend to restrict the quantity of ore that can be moved from the mines to the coast. The only practical way of transporting the ore is via the Berbice River, which is not navigable to seagoing vessels. The mined ore is trucked to Kwakwani, where it is crushed and washed and loaded onto pontoon barges, each with a capacity of only 400 tons. Shallow-draught tugs move a train of several loaded barges through a ¾-mile canal to the river, down a 12-mile channel dredged in the river, and thence to the drying plant and shipping terminal at Everton near the river mouth. The 120-mile river journey takes about 24 hours. A bar across the Berbice Estuary limits overseas shipping to the use of very small freighters. A test cut was dredged through the bar during 1963, and preliminary determinations of the silting rate indicated a channel could be maintained by dredging every 2 or 3 years. The channel in the upper reaches of the river is maintained by an 8-inch hydraulic dredge.

In addition to shipping problems, Reynolds was handicapped by the general strike and other labor disputes during 1963, and its total output of dried bauxite amounted to only 300,695 metric tons, compared with a record output of 479,169 tons in 1962. The 1963 output included 269,717 tons of metallurgical-grade and 30,978 tons of chemical-grade bauxite. About 95 percent of the ore came from the Mombaka mine. Most of the remainder came from the Wong Lease, and a little came from the Bissaruni mine.

Gold.—Although the total quantity of gold recovered in 1963 was about 50 percent greater than in 1962, gold mining in British Guiana continued to be of minor importance, compared to the more productive period before 1959. From 1884 through 1963 British Guiana produced almost 3.4 million ounces of gold or an average of more than 48,500 ounces per year. However, annual output has been only a fraction of this average since 1958, when all dredging operations ceased. Although dredging has been an important production method, it has accounted for no more than 15 percent of the total gold output, whereas from 80 to 85 percent has been recovered by hand methods from thousands of small workings; some gold also has been won by milling ores from a number of small lode deposits and some by large-scale hydraulicking methods.

The last gold dredges to operate in the colony were those of British Consolidated Goldfields, Ltd., which were working gravels on the Potaro and Konawaruk Rivers when the company was forced into receivership in 1958. This company produced 10,578 of the 16,491 ounces of gold produced in the colony in 1957. The demise of the venture resulted from attempts to maintain too large an operation for the yield attainable. Attempts to persuade other companies to purchase the equipment and to resume dredging operations apparently have been unsuccessful, and at last report the two dredges and the hydroelectric facilities installed at Tumatamari Falls still were on a care and maintenance basis.

Most, if not all, the gold recovered since 1958 has resulted from the efforts of individual prospectors. Their combined output has been abnormally low in recent years for the reason that many prospectors previously engaged in the search for gold have been lured to the newly discovered diamond fields.

Manganese.—Northwest Guiana Mining Co., Ltd., partly owned by Union Carbide Corp., produces manganese ore from deposits at Matthews Ridge about 15 miles southwest of Arakaka in the Northwest District. About 250 tons of ore was exported to the United States in 1956, but large-scale production was not begun until 1960. Output increased from nearly 125,000 metric tons in 1960 to more than 275,000 tons in 1962 but had to be cut back sharply to less than 143,000 tons in 1963 because of low prices that prevailed for lower grade manganese ores in that year; production costs in British Guiana were reported to exceed the sales value of the 42 percent ore the company produces.

Development of this large-scale mining operation in an almost uninhabited jungle region reportedly involved an investment of about US$12 million; a large part was spent on constructing a transportation system to move the ore from the interior to the coast for export. A 33-mile railroad was built from Matthews Ridge northward to a transshipment point called Port Kaituma on the Kaituma River. Dredging a turning basin and 2.5 miles of canal, as well as extensive dredging along the Kaituma River, was necessary to provide a suitable waterway for the vessels of about 3,000-ton capacity used to transport the ore via the Kaituma and Barima Rivers to a transfer station in Trinidad. The company also built Pakera Village near the mine and washing plant to provide housing and other facilities for em-

758-002—65——17

Digitized by Google

ployees and noncompany personnel engaged in local governmental activities.

The ore bodies at Matthews Ridge are similar to those in Amapá and Minas Gerais in Brazil in that they resulted from the supergene enrichment of manganiferous horizons in Precambrian sedimentary rocks. A reasonably accurate estimate of ore reserves is not available; however, one source has indicated a magnitude of 6 million tons. Similar deposits of manganese oxides are known to occur at Pipiani, Tassawinni, Saxacalli, and other localities in the northern part of the colony. Some of these occurrences have been explored superficially, but thus far no other deposits have been found that compare in size and grade to those at Matthews Ridge.

NONMETALS

Diamonds.—Diamond miners recovered nearly 100,000 carats of gem and industrial diamonds during 1963, thus maintaining their high level of productivity for the 4th successive year. The Mazaruni District continued to be the most productive, increasing its contribution to 78 percent of the total carats and 77 percent of the total number of stones produced during the year. However, output decreased in the Potaro and Cuyuni Districts, fell markedly in the Rupununi District, and no stones at all were reported from the Northwest and Berbice Districts.

The revival in diamond mining in the colony began in 1958 with discovery of diamonds in the gravels of the Kurupung River above the escarpment of the Pakaraima Plateau. Previously most diamond recovery in the Mazaruni District was restricted to the lower areas. As a result of this new find, diamond output almost doubled in 1959 to the highest level since 1930. Another plateau discovery was made in 1960 on the Ekereku River in the Cuyuni District, and several subsequent finds have been made in adjoining areas in both districts. Access to these areas has been facilitated by trails cut by the Geological Survey and by the establishment of landing facilities for small aircraft.

Diamond recovery in British Guiana is largely the realm of individual prospectors although a few more or less organized groups also participate. Diving equipment is used by some miners to gather gravels in deep water. The water-dogging technique usually is employed in shallow water; one miner reportedly recovered 2,000 carats of stones during 3 months of work on the upper Ekereku River. Some attempts have been made to work diamondiferous gravels by dredging but results have been poor thus far, mainly because the equipment used was not suitable. Several groups are planning to introduce more advanced types of suction dredges into the diamond areas. If successful, they may increase production substantially.

Total diamond production from 1901 through 1963 amounted to 3,199,484 carats. Peak output was in 1923, when 214,474 carats was recovered. Most of the stones found in the colony were small, averaging 7 or 8 stones to a carat. Many very small stones probably are missed by the miners or are ignored because of their slight value. The largest stone found was a crystal of bort weighing 97 carats, whereas the largest stone of gem quality weighed 56.75 carats. The Lands and Mines Department has estimated that about 60 percent of

Digitized by Google

the stones recovered in recent years were of gem quality. Apparently, gem diamonds are predominant in some areas, whereas industrial stones are more common in others.

Construction Materials.—Cement and lime must be imported but sand, stone, and clay are available locally for use in concrete, for road metal, and for construction of dikes and seawalls. Various types of stone have been quarried intermittently in the general vicinities of Bartica and Mackenzie and along the road from Bartica to Potaro. The gabbro quarry at Monkey Jump on the Essequibo River south of Bartica is considered one of the better sources of stone for the Georgetown area. The Public Works Department operates a crushing plant in Georgetown and sells graded products for aggregate.

Relatively small amounts of clay are produced for making brick and pottery; however, burnt clay has been widely used as a dressing for the main roads. Some marl imported from Barbados also has been used to surface roads, and bauxite has been used as a binder for some roads in the Mackenzie area. Approximately 100 miles of public roads have been surfaced with imported asphalt and road oils.

MINERAL FUELS

Oil companies have made geophysical surveys in the coastal and offshore areas of British Guiana and a few exploratory wells have been drilled on the mainland. The explorations made thus far have failed to indicate the presence of commercial amounts of oil or gas, although the possibility of finding offshore deposits is not entirely discounted. The latest exploration was an unencouraging marine seismic survey made by the California Oil Company (British Guiana), Ltd., in 1958. This company abandoned its concession in 1960, and no license to explore for oil has been issued since that time; although Gulf States Land and Industries, Inc. has attempted to negotiate such rights for off shore areas adjoining those it is exploring off Surinam.

Petroleum imported from Trinidad is the principal source of energy as the colony has no known fuel resources other than wood. There is a considerable hydroelectric energy potential that is virtually undeveloped; one small hydroelectric plant has been built in a remote mining area but has not been utilized since 1958.

Incomplete data indicate a marked increase in imports of fuel oils during 1962. Fuel oil imports, distillate and residual, are estimated at 2,194,000 barrels for 1962, compared with 1,338,000 barrels imported in 1961. Conversely, gasoline imports decreased from 252,000 to about 200,000 barrels. Kerosine imports increased slightly from 144,000 to about 147,000 barrels.

The Mineral Industry of Chile

By Lester R. Brown, Jr.,[1] and Sumner M. Anderson[2]

GAINS were made in 1962–63 in all major elements of the mineral-production industry except iodine and coal (which declined 8.2 and 7.3 percent respectively), and in at least 7 of the 16 minor elements. In the field of metals, production declined only in lead, mercury, and zinc, which have never been important quantitatively. Among the nonmetallic minerals, production advanced for the important nitrate and phosphate fertilizers, cement and relatively incidental sodium sulfate, kaolin, feldspar, quartz, and lapis lazuli; it declined 22 percent for borates and in proportions ranging from 9 to 2 percent for gypsum, sulfur, salt, barite, and limestone.

Metal, mineral, and mineral fuel production and processing dominate the economy of Chile, and copper dominates its foreign trade and contributes vitally to the federal budget and to politics. The industry accounted for 82.6 percent (an estimated US$297 million) of total export earnings in 1963. The importance of the mineral industry relative to total South American and world production in 1963 is shown in the following table:

Commodity:	*Share of South American total production, percent*	*World total production, percent*
Copper:		
Mine production, third in world rank	76.7	12.7
Smelter production, third in world rank, first in exports	77.7	11.2
Nitrogen compounds:		
Natural nitrates	100.0	100.0
All types, including natural nitrates	[1] 82.0	[1] 1.0
Iodine	100.0	[1] 60+
Iron ore	21.7	1.7
Molybdenum, third in world rank	83.5	7.3
Bituminous coal	24.8	(2)

[1] Estimate.
[2] Negligible.

The mineral industry of Chile, exclusive of the mineral fuels, is the largest in South America. Domestically the monetary importance of mining follows that of manufacturing, agriculture, and transportation and communications. Normally mining, which employed approximately 67,000 people in 1963, accounts for 11.5 percent of the national income and 9.7 percent of the gross national product (GNP), but values have not been made available to show what portion of manufacturing is represented by copper and iron and steel production, cement and other mineral processing and manufacturing, and petroleum

Digitized by Google

refining, all important sectors of the mineral industry. Detailed value figures for 1963 have not been received; according to the International Monetary Fund, the value of total exports in 1962 was US$530 million, of which US$471.6 million [3] or 89 percent was mineral exports. Of the mineral exports, 77 percent was copper, 12 percent iron ore, 6.5 percent nitrates, 2.1 percent molybdenum, and 0.8 percent iodine—all shipped by the large mining companies; 9 other mineral items comprised the remaining 1.6 percent.

The dominance of copper has made its price and international demand of prime importance to the Chilean Government, which has exercised increasing control over marketing policy and production rates of the industry. The Chile Exploration Co. and Andes Copper Mining Co. (subsidiaries of The Anaconda Company) and the Braden Copper Co. (subsidiary of Kennecott Copper Corp.) comprise the copper segment of the large mining category ("gran minería"). They pay direct taxes amounting to roughly one-fifth of the total tax receipts of the country and supply approximately 68 percent of the foreign exchange needs. Miners in the medium and small categories are subject to separate and lower tax rates. Additional millions enter the economy through purchase by these companies of nearly half their operating requirements in the domestic market (US$32.5 million in 1961) and from special levies for road construction, irrigation, housing, education, social services, provincial and municipal improvements, the armed forces, and assistance to the economic and industrial development program of the Government.

The 5-year period 1959–63 showed a 141 percent rise in the GNP from Esc4,077 million to Esc9,827 million and a 9.7 percent increase in estimated population from 7,411,000 to 8,133,000, giving an increase of 51.9 percent in GNP per capita from Esc545 to Esc828. The net foreign balance (inflow minus outflow) quadrupled from Esc86 to plus Esc342 million. These suggestions of progress have been offset by (1) inflation, as seen in the 51 percent devaluation of the escudo from an official market exchange rate of Esc1.053 to Esc2.146 per US$1 and a 97.1 percent rise in the Santiago cost-of-living index from 139 to 274 (based on 1958=100); (2) an increasingly unfavorable trade balance; and (3) a declining balance of payments (minus US$48 to minus US$190 million on goods and services).

To improve the economy, Chile has adopted a 10-year plan, 1961–70, for raising the gross domestic product (GDP) by 5.5 percent a year or the per capita GDP by 3 percent a year. The total planned investment is Esc9,500 million; the investment scheduled for mining is Esc1,726 million. Copper mining is expected to absorb Esc523 million; iron-ore mining, Esc85 million; and nitrate mining, Esc20 million, with the hope of increasing production of those products by 54, 124, and 8 percent, respectively. The plan provides for investment of Esc405.9 million in expansion of the petroleum industry and Esc33.3 million in the merged Lota and Schwager coal mines. Progress toward financing the plan was made in 1963 when The Anaconda Company and Kennecott Copper Corp. agreed to invest about US$250 million in new electrolytic refinery installations, contingent on a tax freeze and lifting

[3] 533,131,427 Escudos (Esc), converted at a calculated average official market exchange rate of Esc1.1325=US$1.

Digitized by Google

special additional taxes of 5 and 8 percent on income imposed in 1960 and 1961. The Canadian Foreign Ore Development Corp. agreed to put US$30 million into developing the Cía. Minera de Santa Fe iron mines and another US$5 million for opening its Santo Domingo copper mine near Antofagasta. In December 1963, an agreement was signed between Chile and the Alliance for Progress in Washington authorizing the Agency for International Development to provide for U.S. citizens and firms investing in Chile insurance against risks of expropriation, war, revolution, and insurrection.

SOURCE MATERIAL

Mineral production statistics have been mainly supplied by the Chilean Ministry of Mines publication, "Anuario de la Mineria de Chile." This was supplemented by export statistics from Comercio Exterior, Dirección de Estadistica y Censos, Santiago, 1961. Annual minerals and iron and steel reports, as well as mineral production questionnaires submitted by the U.S. Embassy, Santiago, furnished most of the information on industrial development. Other sources included: World Oil; Mining Annual Review, 1964, Mining Journal (London), June 1964; and E&MJ Metal and Mineral Markets, February 18, 1963.

PRODUCTION

Chilean official statistics on production of metals and metallic ores and concentrates are reported generally in terms of metal content. Exceptions are iron ore and manganese ore, which are given in gross weights and grades.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Copper:					
In ores and concentrates	28,590	31,630	26,458	35,723	44,079

[2] Estimate.
[3] Data not reported.
[4] Excludes liquid petroleum gas from natural gas plants.

TRADE

Trade data from Comercio Exterior showing country distribution and values in 1961 were the latest available. Partial data on 1962 exports from Embassy sources have been listed separately. Values are given in dollars only when so reported from Chile. Values reported in Comercio Exterior are in gold pesos, an artificial unit used in foreign trade statistics only, to which the Chilean Government assigned an arbitrary value equivalent to US$0.20597 for the year 1961.

COMMODITY REVIEW

METALS

Copper.—The 1963 production of recoverable copper in ore was nearly 1.4 percent greater than that of 1962. More than 84 percent of the 1963 output was from the mines of the three U.S.-owned companies which comprise the copper segment of the Gran Minería, a grouping of large mining enterprises that also includes certain iron ore and nitrate producers. The Gran Minería share of Chilean copper output declined nearly 7 percent in the 1959–63 period.

The largest copper producer of the Gran Minería group has been the Chuquicamata mine, owned and operated by the Chile Exploration Co., a subsidiary of The Anaconda Company. The mine is in Tarapacá Province northeast of Antofagasta.

Large-scale open-pit mining methods continued in use in 1963 but underground mining is expected to begin around 1970. A drainage tunnel 5,700 meters long reached a point 150 meters below the pit bottom in 1961.

TABLE 5.—Copper production distributed by type and producing group
(Metric tons)

Year	Gran Minería					Total	Total Chilean production	Gran Minería percentage of total
	The Anaconda Company			Kennecott Copper Corp., Braden Copper Co., El Teniente mine				
	Chile Exploration Co., Chuquicamata mine		Andes Copper Mining Co., Potrerillos and El Salvador mines					
	Electrolytic	Blister	Blister	Fire refined	Blister			
1959	177,010	100,940	54,800	82,631	81,734	497,115	546,224	91.00
1960	146,997	83,131	78,797	78,565	91,288	478,778	536,446	89.25
1961	153,492	96,158	72,564	62,289	96,629	481,132	550,873	87.34
1962	180,106	95,705	82,465	66,369	98,111	522,756	592,948	88.16
1963	178,947	95,889	88,216	61,800	78,737	503,589	601,070	83.78

The upper oxide ores are treated by a leaching process and the deeper sulfides by flotation concentration. Products of both concentrator plants are smelted and refined at Chuquicamata. Reserves are not officially reported but estimates range from 600 million to 1,000 million tons of ore containing 1.6 percent copper.

The second largest Chilean producer is the underground El Teniente mine, owned and operated by the Braden Copper Co., a subsidiary of the Kennecott Copper Corp. It is at Sewell in the Province of O'Higgins, northeast of the city of Rancagua. All ore extraction is by block caving; the reserve is unofficially estimated at more than 350 million tons of ore containing 1.9 percent copper.

The Braden smelter is at Caletones, about 6 kilometers from the mine, and ore is moved by aerial tramway to the smelter.

The third of the Gran Minería, the El Salvador mine, is in the Province of Atacama and east of the port of Chañaral. It is owned and operated by the Andes Copper Mining Co., another Anaconda

Digitized by Google

subsidiary. The mine was opened in 1959 to replace the worked-out Potrerillos mine. Reserves are estimated to total 375 million tons of ore, with an average copper content of 1.6 percent.

Each of the Gran Minería operations has its own copper smelting facilities. In addition, four other domestic metallurgical facilities processed copper ores in 1963, and a fifth was under construction. In 1963, Chilean smelter output was equal to more than 93 percent of the mine output. All ore produced by the Gran Minería group is smelted in Chile, together with an appreciable amount of that produced by the smaller mines.

TABLE 6.—Copper smelters other than those of the Gran Minería

Plant	Owner and/or operator and location	Remarks
Paipote smelter	Chilean Government, near Copiapo	In 1961, treated 155,335 metric tons of ores and concentrates from medium and small mines.
Chagres smelter	Cía. Minera Disputada de Los Condes, S.A. (Compagnie Miniere du M. Zaita of France); Province of Valparaiso at Llaillay.	Reactivated in 1960 to exclusively treat products of affiliated mines.
Montos Blancos chemical plant and smelter.	Empresa Minera de Montos Blancos (Mauricio Hochschild y Cía., Ltd.); 50 kilometers from Antofagasta.	Initiated in 1961 to exclusively treat products of affiliated mines.
Small matte furnace	Privately owned and operated, treating ores from the Chivas mine, on Lake Buenos Aires.	Remote, isolated location.
Ventanas smelter	Empresa Nacional de Minera, Chilean Government, near Valparaiso. (Scheduled completion, April 1964.)	Plans are underway for additional government projects plus electrolytic refining facilities.

The major mining companies of Chile are required by law to furnish the refined copper needed by the local industry and fabricators. The three Chilean fabricators are: (1) Fabricas y Maestronzas del Ejercito (FAMAE); (2) Manufacturos de Cobre, S.A. (MADECO); and (3) Cobre Cerrillos, S.A. (COCESA). These fabricators reportedly have an annual capacity of 60,000 tons, but production has never reached this figure, apparently because Chilean fabricating costs are high, and operation at capacity would not yield products which would be competitive with imports.

Gold.—Most recent gold production has been obtained as a byproduct of copper refining. Most of the remainder has been from small placer operations in the Provinces of Atacama, Coquimbo, and Antofagasta.

TABLE 7.—Gold production in 1961 by provinces and mine size groups
(Troy ounces)

Province	Major mines	Medium mines	Small mines	Total
Atacama	13,946	2,153	12,789	28,888
Coquimbo		6,008	6,716	12,724
Antofagasta	6,105		1,124	7,229
O'Higgins	4,467	1,381		5,848
Others		1,446	354	1,800
Total	24,518	10,988	20,983	56,489

Iron Ore.—In 1963, iron ore continued to be second only to copper among Chilean mineral commodities in value of production and of

Digitized by Google

exports. In 1962, it accounted for 11.4 percent of the value of production and 12.05 percent of the value of exports.

Most of the high-grade iron ore deposits are in southern Atacama and northern Coquimbo Provinces, in a well defined belt, inland from the Pacific Coast, and extending 580 kilometers from Taltal to Ovalle.

More than 85 percent of 1963 iron ore production came from three companies: Cía. de Acero del Pacífico, S.A. (CAP), Bethlehem-Chile Iron Mines Co., and Cía. Minera Santa Fe.

Expansion of the Huachipato steel plant together with apparent continuing growth in export markets suggests that output should continue to increase; growth in output to date has not been accompanied by any decline in grade.

TABLE 8.—Major iron ore producers in 1963

Company	Cía. de Acero del Pacífico, SA. (CAP)	Bethlehem-Chile Iron Mines Co.	Cía. Minera Santa Fe
Ownership	The Anaconda Company, Kennecott Copper Corp., W. R. Grace & Co., Koppers Co., and 7,200 shareholders.	Subsidiary of the Bethlehem Steel Corp. (United States).	Minerals and Chemicals Philipp Corp., Canadian Foreign Oil Development Corp., and others.
Main mine	Algarrobo	El Romeral, started in 1955. El Tofo, principal producer until 1957.	Carmen.
Location	Province of Atacama, at Guacolda, near Huasco, in Northern Chile.	Province of Coquimbo, 25 kilometers from La Serena.	Province of Atacama, 50 kilometers from Chañaral.
Reserves	70 million measured tons. (Largest of any Chilean property).	16 million tons measured	Between 8 and 10 million tons.
Production	1962 production was 1,622,000 tons. 1961 was the first year of exploitation (open pit). CAP is primarily a steel producing facility, exporting its Algarrobo production and ore purchased by ENAMI. It does not supply the Huachipato plant with feed, buying it all from Bethlehem at cost. The Algarrobo deposit is proving larger than expected.	1962 production was more than 2 million tons. Both El Romeral and El Tofo are open-pit operations. Romeral provides all the requirements of the Huachipato steel plant, which amounted to almost 700,000 tons in 1962.	Equipped to produce 1 million tons per year (open pit). Carmen has a series of endless belts to move the ore from mine to railroad station at Hermantita. Santa Fe also operated several other small mines and purchased ore from other companies. Combined reserves of Carmen and other mines are estimated at 40 million tons.

Iron and Steel.—More than 90 percent of iron and steel output was from Cía. de Acero del Pacífico, S.A. (CAP). This firm is a highly integrated steel company, possessing or controlling virtually all steelmaking elements either by direct ownership or long-term contracts. Steel-ingot-production capacity was rapidly approaching the target of more than 600,000 tons outlined in the 1962–65 productivity improvement program. In 1962 the Huachipato steelworks of the company, in Concepción Province, had one blast furnace, four open hearths, and several rolling mills. The company also had its own coke plant and pipe mills at another site.

In a joint venture with the Ecuadorans, CAP was forming a new steel company in Ecuador. CAP is investing $400,000 (40 percent of the capital), and will supply the new company with semifinished steel from Chile.

Other Chilean steel producers include Armco (Chile) S.A.I. (a subsidiary of Armco International Corp.), near Huachipato, which

Digitized by Google

has a new and modern plant with an output capacity of 30,000 tons of grinding balls; and Metalurgicos Indac, S.A., in Santiago, which is equipped with one electric furnace for scrap remelting as well as various rolling mills, and can produce 12,000 tons of crude steel and 18,000 tons of merchant mill products.

Lead.—Lead production in Chile in 1963 was limited to two companies; the Sucesión Federico Blanc, in Coquimbo Province, and Empresa Minera Aisén in Aisén Province.

Exports of raw ores and concentrates in 1963 were mostly to West Germany; a smaller amount was to Belgium.

The lead smelter of Empresa Minera Aisén has not operated since 1959. Metal production since that year has been from the Dos Rios smelter of Sucesión Federico Blanc in Coquimbo Province.

Manganese.—Output of manganese ore in Chile increased 7.7 percent from that of 1962; the country continued to rank third among South American producers, its output being equivalent to about one-third that of British Guiana and virtually inconsequential in comparison with that of first-ranked Brazil. Two companies, Cía. Manganesos de Atacama and Cía. Manganesos de Chile (Santa Fe), provided almost all of the 1963 output in about equal shares, as they have in each year since 1960; various small mines in Coquimbo and Antofagasta accounted for the small remainder. Indicated average ore grade in 1963 was 45.5 percent manganese.

The largest part of Chilean ore output was processed in Chile for the production of ferromanganese and silicomanganese, most of which has been exported to the United States. The production increase in 1963, in part at least, was attributable to a barter arrangement whereby Chile received surplus agricultural products in exchange for ferromanganese.

Mercury.—The downward trend in mercury production continued in 1963, as a result of depletion of high-grade ores. Mercury deposits lie mainly within a narrow strip extending from Copiapo in the north to Illopel in the south. The only active mercury producer in 1963 was the Los Mantos de Punitaqui gold and copper mine in Ovalle, in the Province of Coquimbo.

Molybdenum.—Molybdenite was recovered as a byproduct in the flotation plants of each of the large copper-mining companies. It generally occurs disseminated in the ores in concentrations of 0.03 percent to 0.12 percent MoS_2, but some small vein deposits have been reported. Production in 1963, in metric tons, was as follows, by company: Chile Exploration Co., 1,361; Andes Copper Mining Co., 891; Braden Copper Co., 794.

In 1962, with an export value of more than Escl1 million, molybdenum ranked fourth in value among mineral export commodities. Exports in 1963 went largely to West Germany, the United Kingdom, the Netherlands, and Sweden.

Silver.—Most silver production is a byproduct of the large copper producers, and a minor amount is recovered from refining lead ores.

In the years 1959–63, Chile ranked third behind Peru and Bolivia in South American silver production, but output amounted to only about 5 percent of the total production of the continent.

Digitized by Google

Zinc.—Since 1950, the largest lead-zinc mine, the Puerto-Cristal property in Aisén Province, has produced more than 80 percent of the lead and zinc.

Empresa Minera Aisén, a subsidiary of CORFO since July 1963, was the only 1963 zinc producer. Output was sent to the Netherlands and West Germany for refining and then returned to Chile.

NONMETALS

Barite.—Production in 1962 and 1963 was distributed among the producers as follows:

Province and producer:	Mine	Production metric tons 1962	1963
Atacama: Sociedad Minera Godoy, Schwenger y Cía.	Copiapo	735	797
Valparaiso:			
Minas y Plantas Pompilio Raggio	Quebrada lo Choapa	180	125
Industria Minera Vassali	Las Mazas	134	97
Total Chilean production		1,049	1,019

Consumers included Empresa Nacional de Petróleo (for drilling mud) and Industrias Bellavista, S.A. (for use in pigments).

The only recorded reserves are about 3 million tons near Caracales, in Antofagasta Province, but no output has been reported from this area in recent years.

Borax.—Fifty years ago, Chile produced 50,000 metric tons of boron minerals per year or about one-half of the world total; however, since 1930, annual production tonnages have been erratic and generally considerably smaller. In 1963 there was only one active producer of borax ore in Chile, the El Loa mine of Borax Consolidated, Ltd., at Ascotán, in Antofagasta Province.

Chilean reserves in known deposits, averaging approximately 30 percent B_2O_3, are estimated to total 10 million tons. They are ulexite-type salina deposits mainly in the provinces of Tarapaca, Antofagasta, and Atacama. Borax is also found in the caliche nitrate deposits where there is an additional reserve of about 19 million tons. The Ascotán reserve is estimated to be 250,000 tons of 27 to 36 percent B_2O_3. This salina, 30 kilometers long and from 3 to 18 kilometers wide, lies in a basin surrounded by inactive volcanos at an elevation of 3,700 meters on the Chilean-Bolivian border. This property has supplied 90 percent of the ulexite mined in Chile.

Cement.—Chile was the fifth largest producer of cement in South America, following Brazil, Argentina, Colombia, and Venezuela. In 1963, output was 8.5 percent of total continental production. The cement plant at Calera, Valparaiso Province, is owned by El Melón Cement Manufacturing Co. and, with a rated capacity of 760,000 metric tons per year, was the largest cement plant in South America. It produced portland, rapid hardening, and white cement. The plant has 8 rotary kilns, and fed with limestone from the underground El Navió mine, 12 kilometers north of the plant.

Cemento Cerro Blanco de Polpaico, S.A., has a plant at Polpaico, about 33 kilometers northwest of Santiago, with an annual capacity

758-002—65——18

Digitized by Google

of about 430,000 tons. The plant, has three rotary kilns, used for producing portland and white cement.

Cemento Bio-Bio, S.A., had the smallest but newest of Chilean cement plants. The operation, having a capacity of approximately 132,000 tons per year, is in Huachipato in the Concepción metropolitan area. Portland and iron portland cement was produced from its two rotary kilns.

Clays.—Of the 1963 kaolin output, 18,165 tons was produced by Cemento Cerro Blanco de Polpaico, S.A., 9,677 tons by Cía. Jesus de Irararte y Bernaola of Santa Cruz in Calchogua Province, and the remainder for several smaller producers. Customers for this product in Chile included Cía. Acero del Pacífico, S.A. (CAP), and Refractarios Lota Green, S.A.

Gypsum.—High-grade (90-percent-purity) gypsum, estimated at 300 million tons, occurs in the northern provinces of the country. Reserves of anhydrite are considerably greater; the Salar de Llamara deposit alone is estimated at 825 million tons.

Approxiately 90 percent of the gypsum produced in 1963 went to the construction industry; the remaining 10 percent, to fertilizer producers. Of the quantity consumed by the construction industry, about 30 percent has been used in cement and 70 percent has been calcined for plaster—about half of which was used for wallboard. The two major producers were Cía. Industrial, "El Volcán," at Puerto Alto, and Cía. Industrias de Yeso Romeral.

Iodine.—In 1963, Chile remained the leading producer of iodine, accounting for more than 60 percent of world production, even though output dropped 8.2 percent from 1962. Chile is the only country that recovers iodine as a byproduct of nitrate production.

The Anglo-Lautaro Nitrate Corp. produced 1,992 tons of the 1963 total; independent companies provided the small remainder.

Iodine occurs in the nitrate-bearing caliche beds in concentrations ranging from 0.03 to 0.12 percent. Crude iodine reserves are estimated at 1.3 million tons.

TABLE 9.—Iodine supply position

(Metric tons)

Year [1]	Production	Exports	Apparent consumption and changes in stocks
1958/59	1,108	1,359	−251
1959/60	1,776	1,330	446
1960/61	1,843	1,724	119
1961/62	2,348	2,278	70

[1] Year ended June 30.

Lapis Lazuli.—Cía. Minera Carén in Coquimbo Province operated the only active lapis lazuli mine in Chile. The mine is at an elevation of 4,500 meters, near the Argentine border and only accessible 3 months of the year. The growing hobby of cutting and polishing semiprecious stones in the United States has offered an expanding market for this material.

Digitized by Google

Limestone.—Most limestone production has come from operations of the two large cement manufacturers, Empresas Industriales El Melón, S.A., in Santiago Province (742,945 tons in 1963), and Cemento Cerro Blanco de Polpaico, in Valparaiso Province (764,472 tons in 1963). A third producer was Cía. Acero del Pacifíco, S.A. (CAP), much of whose output (196,819 tons in 1963) has gone to its steel plant in Huachipato for furnace flux.

No exact data are available on the number of limestone kilns in Chile or on the volume of caustic lime produced. Cerro Blanco operates the biggest kiln with a 35,000-ton yearly capacity.

Limestone reserves in northern and central Chile, total about 300 million tons containing 75 to 80 percent $CaCO_3$, while between Puerto Montt and Cape Horn, there are deposits containing thousands of millions of tons.

Nitrates.—Exploitation of nitrates began in the middle of the 19th century, and for some time thereafter Chile was the principal world source of nitrogen. This continued until the process was developed to make synthetic compounds, using nitrogen from the air.

In 1962, the value of Chilean production of nitrates placed this commodity in third position among mineral products after copper and iron ore, providing 6.31 percent of the total output value. In the same year, exports of nitrates provided 6.5 percent of the value of total exports, again ranking them third after copper and iron ore.

The deposits are in an area 16 to 80 kilometers wide and 700 kilometers long in the northern desert part of the country in the Provinces of Tarapaca and Antofagasta. They are not uniform and range from a few centimeters to several meters in thickness. Reserves of recoverable nitrates have been estimated as high as several hundred million tons.

In 1963, the Anglo-Lautaro, Pedro Perfetti, Iquique, and Victoria nitrate companies were the main producers, the first being by far the largest.

Domestic consumption of nitrates reached almost 20 percent of total production in 1963, compared with only 2.3 percent in 1961.

Phosphates.—*Apatite.*—Commercial deposits of apatite are found in Chile in a belt approximately 240 kilometers by 20 kilometers from Vallenar (on the border of Atacama and Antofagasta Provinces) to just south of Coquimbo.

The sole Chilean producer of apatite is Cía. Salitrera de Tarapaca y Antofagasta, which has operations in Atacama and Coquimbo Provinces. Output of apatite and guano phosphates has not been sufficient to meet domestic requirements for phosphate-fertilizer raw materials, and the quantity of rock phosphate imported is usually greater than domestic production. In 1963, output increased by 10.5 percent from 1962 but was still below tonnages recorded in previous years. Grade averaged 26.5 percent P_2O_5.

Chilean apatite reserves are estimated at 2.5 million tons of 25 to 28 percent P_2O_5 and 3.0 million tons of 10 to 12 percent P_2O_5.

Guano.—All guano production is now limited by law to the activities of the Soc. Chilena de Fertilizantes, Ltda., a government-controlled corporation, organized by Production Development Corp., (CORFO) and the Agricultural Commerce Co.

Digitized by Google

Annual production increased 38 percent in 1963 to the highest level recorded since 1958. Of the total, 18,248 metric tons consisted of the fossil red type, and the remainder was the white or recent type. Most of this came from the Arica and Iquique zone with a minor amount from the Antofagasta area near Mejillones.

Lazulite.—Records do not indicate any lazulite production for the past few years. The only known Chilean deposit is in the Sierra del Combo, 10 kilometers southwest of Copiapo in the Province of Atacama. It is quite extensive, covering an area of 700 by 1,200 meters, containing an estimated 800 tons of ore, averaging 18 percent P_2O_5, and approximately 300,000 tons, averaging 6 percent P_2O_5.

Quartz.—There were six active quartz producers in Chile in 1963, of which the largest was the Soc. Productora de Cuarzo Tilama at Illapel, in the Province of Coquimbo, which produced 38,376 tons, or 51 percent of the Chilean total.

Salt.—Sodium chloride is abundant and widespread in Chile, occurring in virtually all the solars and nitrate deposits.

Production is apparently governed by domestic needs; no exports are recorded. The largest producer, Punta de Lobos Salt Mining Co., operates several mines in the Solar Grande area, south of Iquique. Another is Fistonic Kinast y Cía., Ltd., whose mines in the Solar de Pintadas produce some 6,000 to 8,000 tons annually.

Chilean resources of salt are considered to be 10,000 million tons.

Sodium Sulfate.—Chile remained a small producer of natural sodium sulfate, having reached a peak in 1947 with a production of 114,142 tons. Even though Chile has produced only for domestic consumption, the years of 1959 through 1963 showed considerable overall gain. Major Chilean consumers include the glass industry, fertilizer producers, and the chemical and paper-products industries.

There are two types of sodium sulfate deposits in Chile: (1) Salinas, containing as much as 80 percent Na_2SO_4, and (2) caliche-nitrate deposits, containing 8 to 10 percent sodium sulfate. All the known deposits occur in the Provinces of Tarapaca and Antofagasta. Reserves are estimated at 300 million tons in the caliche-nitrate beds and 3.5 million tons in the salinas.

There were three producers of sodium sulfate in Chile in 1963. The largest, C. A. Minera Canchones, Ldta., near Iquique, produced 20,210 tons of an unknown grade. The Aguas Blancos Mine, near Antofagasta, produced 6,991 tons with a grade of 88 percent Na_2SO_4; Fistonic, Kinast y Cía. of Iquique produced 5,220 tons.

Sulfur.—Chile was the leading South American producer of native sulfur; its production, which has exceeded 55,000 tons annually, constituted less than 1 percent of world production.

The principal producer of sulfur in Chile in 1963 was Soc. Azufrera Aucanquilcha, S.A., in Antofagasta Province. In 1962, this firm, holding reserves of 5.5 million tons of 48 percent sulfur ore, accounted for 51 percent of total Chilean output. The second-ranked producer, Cía. Azufrera Agricola y Commercial Tacora, S.A., produced an estimated 15,000 tons of sulfur from its deposits in Tarapaca Province in 1962. Reserves in the company mines, all on the flanks of Tacora Volcano, are estimated at 2 million tons of 50 percent sulfur ore. The third-ranked producer in the nation, Soc. Azufrera Borlando y Cía.,

Digitized by Google

Antofagasta Province, produced 7,680 tons of sulfur from its 2-million-ton reserve of 50-percent sulfur ore on Chutinza Mountain on the Bolivian border.

The Chilean Ministry of Mines lists more than 100 sulfur mines and deposits, with estimated total reserves of 41 million tons having an average sulfur content of 51 percent. The ore bodies consist of native sulfur in bedded deposits with volcanic ash, tuff, pumice, clay, and gypsum.

TABLE 10.—Elemental sulfur supply position

(Metric tons)

Year	Production	Imports	Exports	Apparent consumption
1959	22,020	1,154	961	22,213
1960	31,397	2,198	813	32,782
1961	44,700	6,180	726	50,154
1962	64,242	(1)	641	[2] 60,000
1963	58,789	(1)	(1)	(1)

[1] Data not available.
[2] Estimate.

Talc.—In 1963, there were two active talc operations in Chile; one operated by O. B. Wolf at Corral in Valdivia Province and the other owned and operated by E. Martín. These properties produced 2,488 and 1,067 metric tons, respectively, in 1963.

MINERAL FUELS

Coal and Coke.—Coal showings, mostly bituminous, occur in Chile from Santiago to Magellanes Provinces, but commercial mining in 1963 was limited to the Provinces of Concepción, Arauco, Valdivia, and Magellanes. Of the total output, Concepción produced 1,267,952 tons (bituminous); Arauco, 315,871 tons (bituminous); and Magellanes and Valdivia together, 134,792 tons (lignite).

The last decade has seen a steady decline in Chilean coal production; however, declining opportunity for replacement by other fuels, coupled with increased mechanization and consolidation of properties, should slow this trend. Decrease in output for the last 10 years was about 25 percent.

The 1963 merger of Cía. Carbonífera y Industrial de Lota and Cía. Carbonífera y de Fundición Schwager, S.A., was a major step to put Chile into a more competitive position. These firms together produced about 74 percent of the domestic total.

Coal exports have been insignificant; 1963 imports, all from the United States, totaled 163,024 tons and were used by the Huachipato steel plant for coking purposes.

Metallurgical-grade coke for use in the Huachipato steel plant is produced from Chilean coal blended with higher grade, low-volatile coal imported from the United States. The ratio of imported coal to domestically produced coal is 2 to 3.

Natural Gas.—Natural gas production increased significantly during the years 1959 through 1963. Output in 1963 was 45 percent higher than that of 1962 and 184 percent greater than in 1959. Gas output is expected to continue to rise to meet anticipated increases in demand.

Digitized by Google

Two refrigerated tank ships are being built to transport liquefied methane, which at the present time is being reinjected due to lack of handling and transporting facilities.

Petroleum.—Active oil exploration in Chile began in the early 1900's. Results of these early studies were not considered sufficiently promising by American and British companies then interested, and activity remained dormant until 1938. The Chilean oil industry was nationalized in that year and placed under the control of the Corporación de Fomento of Chile (CORFO) which initiated an active study program in the Magallanes area that led to discovery of oil at Spring Hill on the main island of Tierra del Fuego.

In 1950, the Government of Chile saw a growing need to consolidate all Chilean exploration and production, and the Empresa Nacional de Petróleo (ENAP) was established as a separate governmental entity. By 1963, technical personnel within ENAP reportedly felt that the rate of discovery of new producing areas had reached a dangerously low point and that the 10-year reserve level could not be maintained. Efforts to improve this situation included exploration drilling near Lebu, 100 kilometers south of Concepción, and testing of sand horizons other than the Spring Hill in the Magallanes area.

The industry has shown production gains during the years 1959 through 1962, despite this low rate of discovery, but output still amounts to less than 1 percent of total South American production. Chile ranked sixth in 1962 after Venezuela, Argentina, Colombia, Brazil and Peru.

All phases of the domestic petroleum industry with the exception of distribution were controlled by ENAP.

A major portion of the crude production has come from the main island of Tierra del Fuego. Data on output by area have been:

	Crude oil production, thousand barrels	
Area:	*1961*	*1962*
Mainland Chile	2,722	5,316
Tierra del Fuego	6,541	6,373
Total	9,263	11,689

The reserves of crude oil of ENAP in the Magallanes area are reportedly 65 million barrels.

The ENAP refinery now under construction at San Vicente Bay, near Concepción, will cover domestic requirements for refinery products when it comes on stream in 1965. It is being built at a cost of approximately US$30 million and is designed to process approximately 35,800 barrels per day.

The mainstay of Chilean refinery production has been the Concon Refinery, in the Province of Valparaiso. Built in 1954, it had a capacity of 44,000 barrels per day in 1963.

ENAP operates a 1,200-barrel-per-day topping plant at the Manantiales field to supply gasoline, kerosine, and diesel fuel to the Magallanes Province. The field also has a compressional absorption plant, which treats approximately 63,450,000 cubic feet of gas per day.

The Cullen gas plant, at the Cullen field, on the island of Tierra del Fuego went on stream to process natural gas in March 1962. It can treat about 98 million cubic feet of gas daily, and also produce

Digitized by Google

propane, butane, and natural gasoline. It is being used for stabilization of crude and repressuring of the field.

Chilean refineries have operated primarily on domestic crude, but substantial imports have proved necessary, as shown in the following distribution by origin of refinery runs to stills:

	Runs to stills, thousand barrels		
Source of crude:	1960	1961	1962
Domestic fields	6, 856	8, 321	11, 366
Imports	3, 585	3, 434	4, 239
Total	10, 441	11, 755	15, 605

The Mineral Industry of Colombia

By Walter C. Woodmansee [1]

MINERAL production was characterized by a large and growing petroleum sector, small but diversified output of industrial minerals, and limited coal and metals output. Oil and gas production has expanded steadily in recent years as newly productive fields have been developed. About 60 percent of the crude oil produced has been refined in Colombia; the remainder has been exported chiefly to the United States and western Europe. Petroleum refinery capacity continued to expand, and further growth has been scheduled. Exploration and development drilling continued to enlarge domestic petroleum resources.

Colombia remained the only important source of gem emeralds, producing about 95 percent of the world total. The only other commodity in which Colombia has been a significant world producer is platinum, output of which ranked the country fourth, after the Republic of South Africa, Canada, and U.S.S.R.

The 1962 mine production, excluding petroleum and natural gas, was valued at more than Col$715 million (US$81 million).[2] Crude oil, natural gas, and petroleum refinery products probably accounted for an additional Col$2,000 million in value of mineral extraction. The extractive industries contributed an estimated 3.5 percent of the gross national product.

Mineral development in Colombia has been hindered by poor access to large parts of the country and a lack of incentives for mineral exploration, mainly due to available supply of most commodities on world markets. Nearly all mineral investigations have been confined to the west and northwest parts of the country—comprising the Andean mountain ranges, intermontane valleys, and coastal lowlands, which constitute about 45 percent of the total land area. The plains and remote tropical jungles of the east and southeast, relatively unimportant economically at present, have not been investigated for mineral deposits to any great degree.

Nearly all the population, transportation facilities, mineral exploration and extraction, and manufacturing are restricted to the west and northwest portion of the country. Exploration has not been extensive in large parts of this region, which is considered favorable for mineral investigations and potential economic deposits. High-grade as well as marginal ore deposits have been discovered in the

[1] Foreign mineral specialist, Division of International Activities.

mountainous areas, but the cost of access, exploration, and development have discouraged investment.

TABLE 1.—Value of mineral production in 1962

GOVERNMENT POLICIES AND PROGRAMS

The Mining Code, adopted in 1887, has been modified and implemented by numerous subsequent amendments and decrees. A new code, better suited to serve the mining industry and the Government, has been proposed and was under consideration in 1963. According to existing laws, any individual qualified under the Mining Code to acquire dominion or ownership of a mine had full rights for mineral prospecting and development, with certain restrictions regarding proximity to dwellings, cutivated areas, and types of mines. The State maintained exclusive ownership of salt mines, sea salt, and a national reserve—including alluvial mines along navigable rivers for 1 kilometer on each side. Mining on these and other State lands has been permitted by concession or by other contract. Other lands may be claimed and exploited subject to terms of the Mining Code and its supplements and amendments. Emeralds, also excluded from the general provisions governing mining claims and concessions, may be worked under permit with governmental inspection. The Banco de la República had authority over the salt mines and some of the emerald mines. During 1962, 162 mineral contracts and 45 permits were in force.

The National Government recently adopted a new mineral policy designed to encourage mineral resource development. This new policy included the following proposals: (1) Increased investigations for mineral deposits, including exploration, development, and marketing; (2) greater governmental financial and technical assistance and foreign technical assistance, credit, and capital; and (3) revision of existing mining laws to simplify and expedite the issuance of mining permits and concessions and to stimulate mineral development.

Digitized by Google

Ministerio de Minas y Petroleos collaborated more effectively with the departmental governments and with private operators in 1963. In addition, foreign technical assistance programs were initiated. The French Government assigned a phosphate specialist to Colombia for 6 months during 1963 to study phosphate deposits and recommend procedures for further studies and development of deposits. The French also planned an aerial photo and ground survey of a 50,000-square-kilometer area considered favorable for mineral deposits.

Technical assistance from West Germany was expected during 1964. As planned during 1963, the German Mission, including a geologist, mining engineer, and test-hole driller, would initially study coal deposits in the Departments of Magdalena, Norte de Santander, and Guajira and, during a second stage, determine coal reserves and commence mine development.

Through an agreement between the U.S. Agency for International Development (AID) and the Colombian Ministry of Mines and Petroleum, a US$4.5 million, 4-year mineral survey was started during the year. Approximately 70,000 square kilometers are to be mapped and studied in the northern, central, and western parts of the country, including the Santa Marta area (Department of Magdalena), central Antióquia, northern Caldas, and parts of Santander, Norte de Santander, Boyacá, and Cundinamarca Departments. AID was to finance US$2 million on a low-interest, 40-year loan. Near yearend, the Ministry issued bid specifications for the mineralogical-geological survey to 11 selected American geological-engineering firms. A geologist from the U.S. Geological Survey was to be assigned as project manager, and a Colombian Technical Advisory Committee was to be appointed by the Ministry to advise the project manager and to review the progress of the program.

The Ministry also has proposed to the Congress the establishment of a Corporación Minera Nacional to encourage and coordinate capital investments in the mining industry. This agency would permit the organization of mixed domestic and foreign capitalized companies for mineral development, exploitation, processing, transportation, and marketing.

A revised bill concerning the newly proposed Mining Code was submitted late in the year and was expected to receive committed study in 1964. Several laws, decrees, and resolutions covering mines and mining activities have been passed since 1960. Some are of a temporary nature. Law 10, a petroleum law passed by the Congress in March 1961, established new royalties and depletion allowances for certain areas, permitted other foreign oil companies to enter the industry of the country, and modified the size of contract areas, exploration periods, rental and work obligations, and duration of concessions. Decree 197 of June 1961, established significant tax exemptions on the mining, chemical, and iron and steel industries as an aid in general economic development.

The National Government had the responsibility for granting concessions to private companies for petroleum exploration and exploitation. It also was involved more directly in the petroleum industry as the largest producer of crude oil and refined products, through the

Digitized by Google

State-owned petroleum company, Ecopetrol (Empresa Colombiana de Petroleos). Petroleum exploration has been permitted free on State lands, but for private lands, notice must be given to the landowner, who is compensated for damages. Under the Petroleum Code adopted in 1960, surface fees and royalties were increased. Oil operators were granted certain tax exemptions and depletion and amortization allowances. Helium or other rare gases discovered became a national reserve. The Ministry may decree any expropriation necessary for the development and welfare of the industry.

SOURCE MATERIAL

All statistical data were derived from official publications of the Departmento Administrativo, Nacional de Estadistica; the Ministerio de Minas y Petroleos; Banco de la República; and the Ministerio de Fomento. U.S. Embassy dispatches from Bogotá also provided useful information.

PRODUCTION

The mining and processing of metallic and nonmetallic minerals has been limited to relatively few commodities, despite the wide diversity of mineral occurrences in the country. The principal metals produced were gold and iron and steel. The Aceriás Paz del Rio, the only fully integrated iron and steel plant in the country, continued to dominate the iron and steel industry. Other iron and steel companies have small-capacity furnaces or mills, and serve local areas. Gold, platinum, and silver were produced by South American Gold and Platinum Co. (New York) and by numerous small placer operations.

A few base metals were produced in small quantities. Juval, Ltda., Bogotá (Department of Cundinamarca) made castings and finished products of zinc, copper, tin, aluminum, and their alloys from imported nonferrous ingots and semimanufactures. Several aluminum mills produced rolled and extruded products. Some of the iron and steel firms also made specialized nonferrous products. Most of the metal supply has been imported, but small quantities of domestic scrap have been generated in smelting and milling operations.

Production of most nonmetallic mineral commodities remained on a par with 1962 or showed some improvement. Output of cement, by far the most important industrial mineral commodity in terms of value of product, continued to expand during the year. The salt industry showed little change from 1962, but expansion appeared necessary to provide salt for a growing chemical industry. Mining of emeralds, another important commodity, has encountered difficulties in recent years, but output increased in 1963—owing to improved mining techniques.

Available data indicate that production of most mineral fuels expanded further during the year, principally crude oil and processed natural gas. Preliminary figures for petroleum refinery products, showing a decline during the year, may be incomplete. The refineries apparently operated at full capacity, and plans were made for needed additional capacity.

TRADE

Total exports of metals and minerals exceeded imports by Col$32.1 million in 1962. Crude petroleum was responsible for this favorable trade balance, accounting for nearly 90 percent of value received from metal and mineral exports.

Colombia continued to import a wide variety of metals and minerals, most in small quantities for limited domestic requirements. Imports of iron and steel mill products accounted for half the total value for all metals and minerals. Receipts of motor and aviation gasoline and lubricants, the only petroleum products imported in large quantities, continued high.

TABLE 3.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961 quantity	1962		
		Quantity	Principal destination	Value (1,000 Col$) [1]
Metals:				
Mercury 76-pound flasks	121			
Platinum, ingots, troy ounces bars. powder and scrap.	20,232	14,100	All to United States	6,777
Uranium and other radioactive minerals.	3

COMMODITY REVIEW

METALS

Aluminum.—Imports continued to be the sole source of aluminum supply. Receipts of bauxite and ingot aluminum increased appreciably during 1962. Bauxite, together with alumina, apparently was utilized for nonmetals industry applications, whereas the ingot and semimanufactures were processed by several rolling and extrusion mills and numerous small shops.

Antimony.—Small mine output of stibnite has been reported intermittently during recent years. Small but growing industrial demand for antimony compounds and alloys has been met largely by imports. Mineral occurrences are known in the Departments of Antióquia, Caldas, Tolima, Cauca, Nariño, Huila and Boyacá, but high local production and transportation costs and relatively low world prices have offered little incentive for development.

Chromite.—The limited production of chromite has been from a single small mine near Medellín in Department of Antióquia. Most has been absorbed in ferroalloys or has entered the export market.

TABLE 5.—Aluminum rolling and extrusion mills, 1963

Company	Location	Products	Remarks
Aluminio Alcan de Colombia.	Cali (Valle)	Sheet, extruded	Alcan affiliate. Rolling-mill production in 1963 after 2 years in construction; capacity 2,200 tons sheet annually. Extrusion section production in 1961; capacity 700 tons. Ingots received from parent company.
Aluminio de Colombia Reynolds, Santo Domingo, S.A.	Barranquilla (Atlantico).	Sheet, foil, tubes	Reynolds Aluminum Co. affiliate. Capacity 2,500 tons. Largest importer of ingot; sells to most other local plants. Both hot and cold rolling.
Industrias Consolidada	do	Extruded	Alcoa affiliate. Capacity 1,800 tons.
Matrini y Caridi, Ltda.	do	Extruded, tubes	Plant constructed 1961.
PERFALCO—Perfiles de Aluminio y Cobre, Ltda.	Cali (Valle)	Extruded	Other light metals also milled.
Vernig	Bogotá (Cundinamarca).	do	None.

Copper.—Colombian copper supply has been provided by imports of the crude and semimanufactured metal and alloys, which during 1962 were increased for the metal and lowered for the alloys. There are copper deposits in several areas, notably the Departments of Magdalena and Guajira, but there has been no reported mining activity. CAMAGRA, a U.S. firm formed by W. R. Grace & Bunker Hill Mining Co., investigated these deposits in 1961 but apparently did not find minable ore.

Copper wire and cables were produced from imported rods by FACOMEC (Fábrica Colombiana de Materiales Eléctricas), a company partly owned by the Phelps Dodge Corp. and Cables Colombiana, Ltda.

Gold.—Gold output, which has been declining since 1960, fell 18 percent during 1963, and values decreased from US$14.2 million in 1962 to US$11.4 million in 1963. Although this output is only about 1 percent of the total world production for the year, Colombia remained the largest gold producer in South America, having an output almost double that of second ranked Brazil.

Production totals are only rough estimates; considerable quantities of gold as well as silver and platinum are contrabanded, leaving the country by means other than through the Bank of the Republic to avoid a 15-percent export tax. South American Gold & Platinum Co. (New York) produced about 60 percent of the total reported output, principally through four subsidiary and affiliated companies—Pato, Frontino, Chocó and Nariño. The Frontino deposit in northeast Antióquia is the only vein type; the others are dredging operations.

In February 1961, the Banco de la República, the sole official buyer of domestic gold, had anounced new purchasing provisions by which an increase in pesos was paid to large producers. Payment was made 25 percent in dollars and 75 percent in pesos. In 1963 the Bank permitted a free market on gold, with no restrictions, from placers in Antióquia, Caldas, Cauca, Chocó and Nariño. The general price was US$35 per troy ounce, but much gold moved clandestinely.

Iron and Steel.—All phases of production showed continued improvement during the year of review. Output of crude steel was 45 percent

Digitized by Google

higher after the 1962 cutback. Imports of most types, especially finished steel, also increased with growing domestic demand.

TABLE 6.—Production of gold and silver by company, 1962
(Troy ounces)

Company	Gold	Silver
Pato Consolidated Gold Dredging	100,524	10,109
Frontino Gold Mines, Ltd	82,373	73,753
Nóvita Mines Corp	27,168	4,146
Minera de Narino	17,156	2,250
Chocó Pacífico	15,330	1,854
Medium and small mining operations	154,276	39,487
Total	396,827	131,599

The industry remained centered around the largest iron ore deposits in the country at Belencito in Department of Boyacá, where Aceriás Paz del Rio, S.A., produced about 90 percent of the crude steel in 1962. Commencing in that year, the iron and steel industry has been emphasized in plans for economic growth. In the General Plan for Economic and Social Development, crude steel production of 270,000 tons and domestic consumption of 420,000 tons were envisioned by 1964. A program submitted to IBRD (International Bank for Reconstruction and Development) in 1962 had called for an increase in crude steel capacity at Paz del Rio from the existing 120,000 tons to 550,000 tons by 1968.

A press report during 1963 announced plans for a new natural gas-fired sheet-rolling mill at Barranquilla (Atlantico) and a new company, Siderúrgica del Caribe, established by a group of Colombian industrialists. This project was approved by the Consejo Nacional de Política Económica y Planeación. Initial scheduled production was 76,000 tons of finished steel per year, mostly plate and tinplate. Investment of US$45 million was anticipated, with the Export-Import Bank providing a loan of US$30 million.

The Council also approved the IBRD-financed expansion program for Aceriás Paz del Rio, S.A., although complete details were not made public during the year. The program was to be implemented in three stages, the first two starting in 1963 if approved by IBRD, at an initial cost equivalent to US$25 million in both local currency and foreign funds. As part of the first stage, ingot capacity was scheduled for increase from 140,000 to 220,000 tons, a 300-ton-per-day, hot-rolling mill was to be constructed, blast furnace capacity was to be expanded to 1,000 tons per day, and a second blast furnace was planned.

Lead.—Much of the limited production of lead concentrates has been a byproduct of Frontino gold-mining operations in the Department of Antióquia. All or most of these concentrates have been exported. In 1961 Frontino sent 313 tons of concentrate to the American Smelting & Refining Co., at Selby, Calif., for smelting, refining and reexport to Colombia.

Small galena deposits scattered throughout the country also have yielded small quantities of lead. Although pig-lead production has not been reported, a few hundred tons appear to have been produced annually by four or five small smelters.

Digitized by Google

TABLE 7.—Iron and steel plants, 1962

Company	Location	Remarks
Acerías Paz del Río, S.A.	Belencito (Boyacá)	Only integrated plant in country. 850-ton-per-day blast furnace; three 20-ton basic Bessemer converters; one 15-ton electric furnace; roughing mill; structural mill; other mills; wire plant. New plate and sheet mill, 1962; capacity, 50,000 tons. 43 coke ovens. Products: merchant bars, structural steel, shapes and sections, rails and wire. Produced 127,800 tons ingot steel, exceeding theoretical plant capacity of 120,000 tons. Ore is Tertiary oolitic hematite, 2 to 6¼ meters thick, average 48 percent Fe, 1 percent P_2O_5. Reserves adequate for many years; one estimate, 50 million tons proved and probable, similar tonnage in possible category.
Empresa Siderúrgica de Medellín.	Medellín (Antióquia)	Mill producing reinforcing rods, tubes, and rail wheels. Receives ingots from Paz del Río. Some secondary production.
Siderúrgica del Muña	Soacha (Cundinamarca)	Subsidiary of Medellín. Uses scrap and Río products, makes structural shapes, angles, tube joints; planned galvanizing plant for tubes. Also iron and special steel products.
Siderúrgica Corradine	Pacho (Cundinamarca)	Two 15-ton-per-day blast furnaces for reducing local iron ore; scrap furnace; few finished products. Ore and limestone from Guayogue; coking coal from La Vieja mine near Pacho.
Siderúrgica de Tibirita	Tibirita (Cundinamarca).	One 20-ton-per-day blast furnace, 6 to 10 tons of gray iron daily. Uses nearby raw materials.

Magnesium.—Magnesium has been extracted from dolomite (12 percent Mg) near Amalfi in the Department of Antióquia. Discovery of other deposits has been reported from time to time, but, insofar as known, no development has been done. Domestic consumption has been very small, a few tons of the imported crude metal and alloys apparently satisfying annual requirements.

Mercury.—Reported production of mercury, appreciable through 1961, was principally from the area of Aranzazu (Caldas). Pato Consolidated Gold Dredging Co. reportedly worked these deposits but withdrew because the operation was unprofitable.

Numerous occurrences of cinnabar have been reported, mostly in the central range of the Colombian Andes.

Nickel.—The Hanna Mining Co. (United States) reportedly conducted a geologic study of nickel-bearing laterites in northern Colombia during 1962, but results of the investigation are not known. The limited demand in the country continued to be met by imports of the crude metal and semimanufactures.

Platinum.—Output of platinum has been from the gold placers of the Department of Chocó, operated by Compañía Minera Chocó Pacífico. This company annually recovers about 15,000 to 20,000 troy ounces, and it had five dredges working during the year. The United States apparently has been the sole market for platinum leaving the country via the Banco de la República.

Silver.—Silver production also is a byproduct of gold placer mining, primarily in the Department of Antióquia, which accounted for about 85 percent of the 1963 output. This production was valued at US$76,030, compared with US$95,700 in 1962.

Uranium.—No production of uranium minerals and other radioactive minerals has been reported, but about 2,000 tons of uranium ores was mined in the region of California, Department of Santander,

Digitized by Google

in 1961, and a few tons of concentrate have been exported in recent years. Mine operator was Compañía Minera de Uranio (MINURANIO). Exploitation terminated in 1962 because of marketing difficulties in the Western Hemisphere. Uranium deposits are also known in other parts of the Department of Santander, as well as in the Cauca Valley (Department of Cauca).

All uranium and thorium deposits in the country have been considered as part of the national reserve, exploitable only by the Government or under contract with the Government. All industrial activity from mine development to distribution has been a public utility. The Instituto Colombiano de Asuntos Nucleares, created in 1955, later became the Comisión de Energía Atómica de Colombia.

Zinc.—There was no output of slab zinc in 1963, because ore and scrap supply was exhausted. The 1960–62 production was at the plant of Metales y Productos Afines, S.A., Bogotá—first electrolytic smelter in Colombia. Total annual capacity was 2,500 tons of slab zinc and several thousand tons of zinc oxide. The ore was produced at Junin, 48 kilometers east of Bogotá. Other possible sources of zinc are the Frontino Gold Mines in Antióquia, where zinc occurs in the tailings, and the Caluranio uranium concession at California (Santander), where considerable zinc is associated with the uranium ore.

NONMETALS

Asbestos.—Production of asbestos has not been reported in Colombia in recent years, although four exploration and mining concessions were granted during 1960. Deposits of chrysotile exist in the Department of Antióquia. Others have been reported in the Departments of Nariño and Caldas and at scattered localtities in the central Cordillera.

Barite.—Production of barite, averaging about 10,000 tons annually, appears sufficient for domestic consumption, which is primarily in oil-well drilling. Deposits of commercial value have been reported in the Departments of Santander, Norte de Santander, Magdalena, Tolima, Huila, Cundinamarca, Cauca, Boyacá and Nariño. The centers of production have been the Los Santos (Santander), where reserves in 1962 were reported to total 300,000 tons, and Abrego (Norte de Santander), where the reserve was about 600,000 tons.

Clays.—Clay production has steadily increased in recent years, especially for use in the cement industry, which has expanded rapidly. Tile, brick, and other construction clays are found throughtout the country. Despite of kaolin have been mined in the Department of Antióquia and the savannah of Bogotá. Numerous other kaolin deposits have been located in the central and eastern mountainous regions.

Cement.—About 10 percent of the cement output has been exported in recent years. This exportable surplus may decrease, however, with the high rate of growth of domestic demand in the construction industry. The annual growth rate of production was 5 to 10 percent during 1959–63.

Digitized by Google

A shortage of supply developed in 1963 and cement companies made plans to invest US$15 million in expansion. This growth has been underway since 1958, when total annual capacity of nine operating plants and two under construction was about 1.8 million tons. By 1960 capacity had increased to 2 million tons, chiefly due to the Cementos Boyacá plant near the Paz del Rio steelworks at Belencito, where 400 to 800 tons of cement were produced daily using a blast furnace slag mixture. In 1962 Cementos del Caribe, S.A., and Cementos Nare, both large producers in the country, announced plans to build a new plant (capacity 100 to 150 tons per day) at Cartagena, where bulk cement could be exported. During 1963 Cementos Boyacá planned expansion to 1,000 tons per day, with new equipment ordered from Denmark. Also, Corporación Financiera Colombiana de Desarrolla Industrial announced plans to finance a new 750-ton-per-day plant at Toluviejo in Department of Bolívar, with production scheduled for 1966; and later in the year plans were revealed for a Cemento del Norte, S.A., plant at Cúcuta in Department of Norte de Santander, which would provide 150 tons per day to the local area.

Diatomite.—The marked increase in output of diatomite was attributed to greater activity at a deposit on the Bogotá plateau, a few miles north of Bogotá (Cundinamarca), where a small processing plant was established. Largest known deposits of diatomite are in the Department of Valle, where a reserve of 50 million cubic meters has been estimated.

Dolomite.—Dolomite output nearly doubled during 1963, owing to mining near Amalfi in Department of Antióquia. Dolomite also has been found at the Muzo emerald mines, north of Bogotá. Production at Amalfi has been hindered by poor transportation facilities; however, roads have been improved to provide better access.

Emeralds.—Reported production of gem-quality emeralds has been shrinking in recent years. The principal reasons for this decline have been the lack of a definite Government policy relating to the mining and sale of these gems in the domestic and international markets, increasing contraband both on local markets and in foreign countries, and limited exploration and discovery of new deposits.

Practically all emeralds in Colombia have been found in an 80-kilometer-wide, northwest-trending belt extending for approximately 330 kilometers from the Vasquez Territory (130 air kilometers north of Bogotá) through Almeida in southwest Boyacá Department. Production continued centered around Muzo and Cosquez in Department of Boyacá, where operations have been under control of Empresa Colombiana de Esmeraldes since 1960, and Chivor in Department of Boyacá, operated by Emeral Mines, Inc., a U.S. firm having a concession in perpetuity from the Colombian Government. The Empresa was organized with Government, private Colombian, and foreign capital, its purpose being to encourage private interest in emerald-mine development. By Decree 1988 of August 1961, a new public corporation, Esmeraldes de Colombia, S.A., was organized to exploit the Muzo and Cosquez deposits on a commercial basis but, as of the end of 1963, this corporation had not been established by law.

The Chivor operation encountered financial difficulties for several years. Administration of the mine was recently reorganized and

Digitized by Google

placed under supervision of seven controllers, all company members. New mining equipment and open-pit methods were introduced in 1962.

Feldspar.—Deposits of feldspar in pegmatites occur in numerous mountain locations throughout the country. The mineral has been mined by crude methods in the Departments of Antióquia, Norte de Santander, and Tolima. Feldspar also has been imported from the United States for use in the glass industry.

Fertilizers.—Increasing quantities of fertilizers, raw materials, and chemicals for use in manufacturing fertilizers have been imported in recent years. Two large factories have been constructed since 1960 to provide for increased domestic consumption: ICF (Industria Colombiana de Fertilizantes, S.A.) at Barrancabermeja (Department of Santander) and ABOCOL (Abonos Colombianos, S.A.) near Cartagena (Department of Bolívar). The ICF plant, situated in a large oil and gas field, has annual capacity for 15,000 tons of nitrogenous and mixed fertilizers, utilizing ingredients from natural gas. The ABOCOL plant, having daily capacity of 650 tons, has produced nitrogenous fertilizers, utilizing materials from a nearby Intercol Petroleum Co. ammonia and nitric acid plant.

An older plant, that of the Paz del Rio steelworks at Belencito in Department of Boyacá, has annually produced 40,000 tons of ammonia, nitric acid, ammonium nitrate, and urea for agricultural and industrial uses, as well as similar quantities of phosphatic slag, containing 18 percent P_2O_5.

By Decree 987 of April 1962, the Government transferred tariff positions on imported fertilizer materials, removing them from the free list. This apparently was done to protect the growing domestic fertilizer industry.

Gypsum.—Output of gypsum has steadily grown, increasing 23 percent during the year, due mainly to greater demand from cement producers. Domestic deposits, although numerous, are commonly of rather poor quality. They occur between Giradot and Bogotá in southwest Cundinamarca Department; Ibaqué and Rovira, Department of Tolima; Gachalá and Macanal, Department of Boyacá; and on the Guajira Peninsula near the Atlantic coast.

Limestone.—Limestone production has increased at an annual rate of 200,000 metric tons in recent years, largely because of the greater cement output. The Paz del Rio steelworks has mined 400,000 to 500,000 tons annually for fluxing and for other uses. This limestone is not of particularly good quality for steelmaking because of high content of silica, aluminum, and sulfur. There are many deposits throughout the mountainous regions of the country, and reserves appear virtually inexhaustible.

Magnesite.—Until recently, magnesite was imported from West Germany and the United States. Since development of deposits in the Department of Antióquia, however, the country has not relied on imports, and during 1963 it appeared to be in a position to offer limited quantities for export.

Salt.—Production of terrestrial salt continued approximately at the 1961–62 rate at Zipaquirá and Nemocón, both in the Department of Cundinamarca, about 30 miles north of Bogotá. Total salt output,

Digitized by Google

including marine salt, was valued at US$43.4 million in 1963. Domestic consumption was 224,000 tons in 1962 and 231,000 tons in 1963.

Rock salt at Zipaquirá and Nemocón has been mined by room-and-pillar methods. The salt is processed at Planta Colombiana de Soda, 6 kilometers from the mine, where it is delivered as brine by pipeline and truck. Plant capacity in 1962 was 1,500 cubic meters of brine daily. The rock salt and brine also have been delivered to many small private refineries.

Output of marine-salt evaporite, produced by hand methods along the Caribbean coast of Guajira Peninsula, decreased by 50 percent during 1961–63, mainly because fewer people have been engaged in this activity. A small quantity also was produced at other salinas between Barranquilla in Department of Atlantico and Cartagena in Department of Bolívar.

All rock salt mines, marine salinas, and other salt deposits are the property of the National Government and have been exploited by the Banco de la República, Concesion de Salinas, under agreement with the Government.

In recent years production of salt has exceeded demand for human and industrial consumption in the country. A new chemical plant under construction at Cartagena in Department of Bolívar, which is scheduled for operation in 1966, is expected to use 500 to 600 tons of salt daily, which would necessitate a production increase of about 50 percent during 1964–66.

Sulfur.—Compañia Industrias Puracé has produced all Colombian sulfur in recent years from a deposit at the base of the extinct volcano Puracé, near the city of Popayán, Department of Cauca. The sulfur occurs as impregnations and fracture fillings in porous Pliocene andesite and dacite tuffs. Drilling in 1961–62 revealed four mineralized zones, and reserves were estimated at 6 million tons containing 30 percent sulfur. As of 1963, 10 autoclaves had been installed, and plans were made for expansion of annual production to 18,000 tons.

Imports of crude sulfur were prohibited by the Government to protect domestic industry. Consumption was about 15,000 tons in 1963, largely in sulfuric acid, or 2,000 tons more than was produced. Because of rising demand, the Government licensed imports of refined sulfur with a tariff of Col$200 per ton and a surcharge of 20 percent ad valorem c.i.f., which raised the price of imported refined sulfur to Col$525, approximately that charged by Puracé.

MINERAL FUELS

Coal.—Coal has been one of the chief mineral commodities exploited for domestic consumption in Colombia. Coals range in rank from subbituminous to bituminous and are widely distributed throughout the country. Reserves and potential resources are enormous. Estimates have placed Colombian reserve from 20 to 40 billion metric tons, perhaps greater than the combined total of other South American countries.

Production has gradually expanded with general industrial growth. About 70 percent of the coal output has originated in the Departments of Cundinamarca and Boyacá in recent years. The Paz del Rio

Digitized by Google

steelworks produced an estimated 600,000 to 800,000 tons of coking coals in 1963 from captive mines. These coals contain excessive ash, and washing has been necessary in preparation of coals for the coke ovens.

Efforts have been made in recent years to interest foreign investment in coal development. Improved inland transportation facilities, port facilities for bulk loading, and mine mechanization would be necessary for any large-scale planned development.

The Instituto de Fomento Industrial investigated the El Cerrejon and Palmarito coal deposits on Guajira Peninsula, near the Venezuelan border, during 1960–61. A report placed proved and probable reserves at 250 million tons of high-volatile bituminous coal, which would require blending with low-volatile coals for coking. Japanese industry has expressed interest in these deposits, but the low-coking qualities may hinder development in the near future.

Coals in the Cauca Valley (Department of Cauca) will be surveyed by AUTECO, a Belgian company acting on a technical mission. The project is sponsored by the United Nations Special Fund and the Colombian Government.

Crude Oil.—Output of crude oil recovered considerably from the decline of 1960–62, mainly due to the new Payoa and Provincia fields in the Department of Santander and the Cúcuta field in the Department of Norte de Santander. Exports continued high during 1962, the latest year for which data are available, although lower by 3 million barrels. Of 98 new wells started, 83 were completed, 10 were abandoned, and 27 were productive in 1962. Nearly 708,000 feet were drilled.

Concession activity remained at a relatively low level in 1962, compared with 1960 when 93 exploration and exploitation agreements were in effect. The main reason for this reduction in activity was the passage of new oil legislation in 1961 and a resulting "wait and see" attitude of foreign oil companies.

TABLE 8.—Operating petroleum companies and their concessions, in 1962

Company	Number in exploration status	Number in exploitation status
Intercol—International Petroleum (Colombia) Ltd.	11	3
Ecopetrol—Empresa Colombiana Petróleos	4	1

Colpet—Colombian Petroleum Co.	1	3
Richmond Petroleum Co. of Colombia	4	----
Magdalena Oil Co.	1	----
Other	2	1
Total	42	17

Late in 1962, two new crude pipelines were brought into operation, both serving the Payoa field. Ecopetrol-Colombian Cities Service completed a 10-inch line, 60 kilometers long, carrying 42,000 barrels per day to the Ecopetrol Barrancabermeja (Santander) refinery. Intercol-Sinclair-British Petroleum completed an 8-inch, 53-kilometer line, having a capacity of 30,000 barrels per day, in Department of

Digitized by Google

Santander from Provincia to the Andean Pipeline Co. line at Yariri on the Rio Magdalena.

Puerto Salgar	Bogotá	143	Do.
Puerto Berrío	Medellín	182	Ferrocarril de Antióquia.
Buenaventura	Cali	98	Oleoducto del Pacífico.
Natural gas lines: Cicuco	Barranquilla	249	Gas Natural Colombiano, S.A. (Mobil, Texas, Colpet, others).

During 1963 Standard Oil Co. of California awarded a contract to Williams Bros., Tulsa, Okla., for construction of a 10-inch, 480-kilometer crude oil line from its Rio Zulia (Department of Norte de Santander) field to Santa Marta (Department of Magdalena) on the north coast. Work was scheduled to begin late in the year. The Rio Zulia discovery well was completed in 1962; by the end of 1963, 14 wells had been completed, and a productive area of 2,000 acres had been delineated.

Exploration during 1962 was concentrated in the El Roble and El Conchal (Intercol-Sinclair-BP) and the Payoa (Ecopetrol-Cities Service) concessions, all in the middle Magdalena valley, Department of Santander. These operations confirmed extensive deposits discovered in 1960. Colpet discovered a new field in its Cicuco (Bolívar) concession, and Richmond Petroleum Co., after 40 years in Colombia, struck oil in 1961 at its concession near Cúcuta, Department of Norte de Santander. During 1962 Intercol continued development drilling in its fields in the Departments of Cordoba and Bolívar.

Oil was discovered in the Department of Putumayo in southwest Colombia in 1963, and development drilling continued at yearend. The operation was a joint venture of Texas Petroleum Co. and Gulf Oil Corp. Texas held 2.5 million acres of concession in Putumayo. The first wildcat hole on an extensive anticline 48 miles southeast of Pasto, Department of Nariño, was drilled to 6,440 feet and encountered several pay sands. Initial yield was 2,000 barrels per day, but final tests had not been carried out because of a lack of tankage. A second well was spudded, and two additional drill rigs were to be placed in operation. Earlier drilling by Texas Petroleum Co. in the adjacent Department of Caqueta had been unsuccessful.

Digitized by Google

Refined Products.—Refinery output of most petroleum products was reduced from the 1962 peak, although consumption continued an upward climb. Daily refinery capacity was nearly 84,000 barrels from five refineries in 1962. Refinery throughput was 30.5 million barrels, compared with nearly 28.3 million barrels in 1961, while output was nearly 30 million barrels, 2.3 million barrels more than in 1962.

TABLE 10.—Salient statistics of the petroleum industry

		1960	1961	1962

Processed to other products	do.	4,034	3,810	4,041
Employment:				
Concessions	number of persons	11,028	9,590	9,535
Pipelines	do.	1,361	1,160	1,130

[1] Includes losses and processed gas flared; therefore total treated plus flared is greater than well production.

Late in 1962 a Mobil International Co. and Shell-Condor, S.A., partnership filed notice with the Ministry of Mines and Petroleum of intent to build a US$35 million, 16,000-barrel-per-day refinery in 1963. At approximately the same time, Ecopetrol, the Government-owned company, also filed with the Ministry for either a new refinery or a major expansion of its Barrancabermeja installation to 75,000 barrels per day. Both proposals have been under consideration by the Ministry. The final decision awarding the contract for this needed additional capacity either to the national company or the private company would no doubt affect the flow of new investment in the oil industry.

Natural Gas.—Well production of natural gas appears to have decreased considerably during 1963, although definite data are not available. Marketed production was 12 billion cubic feet, as compared to 13.8 billion cubic feet in 1962. The two major processors, Ecopetrol and Colpet, produced liquefied petroleum gas, natural gasoline, and butane at their El Centro (Department of Santander) and Tibú (Department of Norte de Santander) plants, respectively. Intercol at Cartagena in Department of Bolívar and Ecopetrol at Barrancabermeja also produced liquefied petroleum gas. A Colpet gas refinery at Cicuco in Department of Bolívar went into production in April 1962. This refinery has daily throughput capacity of 35 million cubic feet and output capacity of 25,000 gallons of liquefied petroleum gas and 13,000 gallons of natural gasoline. The latter has been used chiefly for mixing with crude oil for export, but Colpet reportedly has been experimenting with its use in making motor gasoline. Shell-Condor,

Digitized by Google

S.A., and Antex Oil and Gas, Inc., continued negotiations for a gas refinery, capacity 30 million cubic feet daily, at the Shell El Difícil field in Department of Magdalena in 1962. Such a plant would increase output of processed natural gas by about 50 percent.

TABLE 11.—Principal petroleum companies

Company	Production of crude oil in 1962 (thousand barrels)	Refinery location	Crude oil throughput in 1962 (thousand barrels)	Daily capacity (barrels)	Remarks
Ecopetrol—Empresa Colombiana de Petróleos.	12,675	Barrancabermeja	13,190	41,500	Wholly Government-owned. Crude oil mainly from El Centro field, 24 kilometers from refinery; 1,170 productive wells; average daily production 30,000 barrels. Also received crude from Shell-Condor and Cities Service at Payoa.
Intercol—International Petroleum (Colombiana), Ltd.	1,389	Cartagena	11,530	33,000	Crude oil from Sinclair-B. P. Exploration, Inc., field, and Texas Puerto Niño field.
		La Dorada	1,412	5,000	
Colpet—Columbian Petroleum Co.	14,160	Tibú	611	2,500	Largest domestic crude oil producer; crude largely exported; small quantity went to Tibú refinery; 296 productive wells. Company also has small refinery at Cicuco which produces liquefied petroleum gas; 17,000 barrels annual capacity. Cicuco oilfield had 12 wells; produced 15,000 barrels per day. Subsidiary South American Gulf Oil Co. is export agency. About 32,000 barrels per day exported.
Texas Petroleum Co.	11,711	Guamo	758	1,800	Oilfield at Puerto Niño; output 33,000 barrels per day; 269 productive wells. Crude went largely to Intercol Cartagena refinery.
Shell-Condor, S.A.					Oilfield at Casabe; 15,000 barrels per day crude produced; 385 wells; largely exported; some went to Ecopetrol refinery.

The Mineral Industry of Ecuador

By Sumner M. Anderson [1] and Lester R. Brown, Jr.[2]

ECUADOR increased the production of most of its metals and minerals in 1963. The only significant exceptions were quantitative declines of 4.2 percent in the output of petroleum and 4.9 percent in the output of silver, but these were not enough to prevent an overall increase of 15.1 percent in the total value of all its mineral products, estimated at 161,133,000 sucres (US$8,952,000) in 1962 and 180,302,000 sucres (US$10,302,000) in 1963. Cement was by far the most valuable product, representing 58.7 percent of the total and two-and-a-half times the combined value of crude petroleum and natural gasoline.

Ecuador makes no appreciable contribution to the world supply of any mineral, and its mineral industry domestically contributes only 1.1 percent to a gross national product (sucres 16,560 million, or US$911 million in 1963) sustained 37 percent by agriculture, forestry, and fishing; 28 percent by commerce, transportation, and construction; and 26.5 percent by services and other activities.

It cannot be stated positively that Ecuador is devoid of major natural mineral resources but only that nothing of outstanding present commercial importance has been revealed by the intensive application of modern exploratory techniques to relatively limited portions of the country's area. The geologic position of the country between the mineral-rich regions of Peru and Colombia continues to offer encouragement to ultimate discoveries of importance, but exploration is extremely difficult in extensive areas, potentially mineral bearing, that are covered with dense forests or marked by Quaternary volcanic or sedimentary deposits. A comprehensive summary of presently known deposits of actual or potential economic interest was published in 1962.[3] Exploitation of deposits that might otherwise be economic is greatly hampered by inadequacy or total absence of transportation facilities and available sources of power.

GOVERNMENT POLICIES AND PROGRAMS

The per capita GNP increased at a slightly faster rate than population in the years 1959–62. The Ecuadoran Government endeavored to improve this progress by issuing the Emergency Decree of August 17, 1962, offering special inducements for expanding industrial transformation of raw and semimanufactured materials to finished products

for both domestic use and export, and for the adoption of assembly line production methods in industrial plants.

SOURCE MATERIAL

In addition to the references cited elsewhere in the chapter, economic and background data were obtained from: Focus (American Geographical Society, New York, v. 9, No. 6, February 1959, pp. 1–6; and from Basic Data on the Economy of Ecuador (Overseas Business Reports 64–74, U.S. Department of Commerce, June 1964, pp. 1–10).

PRODUCTION

Data on production have been supplied by industrial and Ecuadoran Government sources through the collecting facilities of the U.S. Embassy at Quito.

TABLE 3.—Imports of metals and minerals, 1962—Continued

(Metric tons unless otherwise specified)

Commodity	Quantity	Principal sources	Value, sucres
Mineral fuels:			
Coal	220	All from West Germany	318,467
Coal and other tars and pitches	134	United Kingdom 131; West Germany 3.	223,482
Coke	161	United States 52; West Germany 50; Portugal 40.	245,963
Petroleum refinery products:			
Gasoline thousand 42-gallon barrels.	90	(1)	(1)
Kerosine do	1,438	(1)	(1)
Distillate fuel oil do	5	(1)	(1)
Residual fuel oil do		(1)	(1)
Lubricants, including greases. do	52	(1)	(1)
Other do	105	(1)	(1)
Total do	1,690	(2)	39,348,970
Total value, mineral fuels			40,136,882
Total:			
Value of metal and mineral imports			164,418,007
Value of all imports			1,748,656,374
Metals and minerals share in total imports. percent			9.4

[1] Data not available.
[2] Distribution of products not reported on a volumetric basis; of the total of 12,541 metric tons imported, the United States supplied 9,224 tons and the Netherlands Antilles 1,791 tons.

COMMODITY REVIEW

METALS

The greater part of all the metals and metallic ores ond concentrates that have been produced in Ecuador have come from two rather widely separated mining areas— the Macuchi mine near the foot of the western Andean slope in the Province of Cotopaxi, and the Portovelo mines at Zaruma in the southern Province of El Oro. The Macuchi mine yielded 24,250 metric tons of copper and from 95,000 to 130,000 ounces of gold while worked by the Cotopaxi Exploration Co. (a subsidiary of the South American Development Co.) between 1941 and 1950 from 472,156 tons of ore. Ore from the main mine level averaged 5 percent copper, 0.27 ounces-per-ton gold, and 0.30 ounces-per-ton silver. The commercial ore was exhausted in 1950, and the mine was shut down, leaving an estimated 139,000 tons of mineralized but submarginal material. The South American Development Co. operated the Portovelo mines continuously from 1892 until 1950 when ore values less than 0.4 ounce of gold per ton ceased to be economic and the mine was closed. The remaining material contained approximately 0.22 ounce of gold and 1.86 ounces of silver per ton, 0.24 percent copper, 0.32 percent lead, and 0.4 percent zinc with traces of cadmium.

Closure of the mines presented a serious economic and social problem to the local mining communities. The Ecuadoran Government purchased the company's equipment and sponsored the organization in January 1952 of CIMA (Compañía Industrial Minera Asociada, S.A.) with 35 percent of the shares purchased by the municipality of Zaruma, 35 percent by a management group of private individuals, and 30 percent donated by the government to ex-employees of the

Digitized by Google

South American Development Co. with 10 years or more of service. Except for insignificant amounts of placer gold, all the gold, silver, and concentrates of copper, lead, and zinc (with associated recoverable cadmium) produced since 1951 apparently have been by CIMA from the properties abandoned by the South American Development Co. at Portovelo; there is no positive evidence of a comparable revival of Macuchi. The Portovelo gold occurs in quartz veins associated with galena, sphalerite, pyrite, and chalcopyrite.[5] Milling facilities at the mine include a cyaniding plant.

NONMETALS

Cement and Lime.—The cement industry has grown rapidly in recent years, and Ecuador has attained self-sufficiency in the production of portland cement but still depends on imports to fulfill its very minor requirements for other types of cement. Production has been from two plants.

A very small cement plant erected in 1922 at San Eduardo near Guayaquil, Guayas Province, was acquired by the Ecuadorian Corporation, Ltd., of New York in 1934, which organized Cemento Nacional C.A. as an operating company. The old plant was replaced by second-hand equipment from the United States, that had a 36,000-ton annual capacity, which has since been gradually replaced and expanded to the present modern dry-process plant of 285,000 tons (6 million 94-pound bags) annual capacity. This plant currently is supplying 80 percent of total Ecuadoran cement production. The company has its own nearby source of limestone, and gypsum and iron sand are available within 100 miles of the plant. The cement is marketed under the brand name "Rocafuerte" at a wholesale price of 17.50 sucres (US$0.97) per bag. The company employs about 200 laborers and 66 office employees.

In 1956 the National Development Bank (Banco Nacional de Fomento), a government institution, opened the Chimborazo cement plant northwest of Riobamba in Chimborazo Province. Production, probably close to the designed capacity of 45,000 tons per year, serves a highland area that has poor transportation facilities to the coast. Extensive limestone and clay deposits are available locally for raw material. Both this plant and that of Cemento Nacional are fueled with domestic fuel oil.

A privately owned 10,000-ton plant called Guapan, near Azogues, Cañar Province, was constructed in 1963 and expected to be in operation in 1964, producing portland and some white cement from local deposits of limestone and travertine. The plant is to be fueled by lignite.

Lime is burned in many small kilns throughout the country, the largest of which is the plant of Fábrica de Cementos Cerro Azul, C.A., near Guayaquil, which has a daily capacity of 10 tons.

Gypsum.—The small amount that is produced in Ecuador goes for making cement. It is handpicked from lacustrine clays near the Cemento Chimborazo plant and from certain marine beds near the Rocafuerte plant.

Digitized by Google

Salt.—Salt is the most important nonmetallic mineral produced in Ecuador. Producers of salt by the solar evaporation process are known in the following localities:

Locality:	*Province*
Charapoto	Manabí.
Salina (largest)	Guayas.
Punta Arena	Do.
Payana	El Oro.
El Morro and San Miquel	Guayas.

In addition rock salt deposits found on the Galapagos Islands, are presently under exploitation by Industrial Salinera Inversionista Dariegas C.A., which invested US$500,000 in the purchase of equipment for mining, refining, and iodizing.

On August 13, 1963, the government salt monopoly was abolished, releasing producers and buyers to operate in a free market throughout Ecuador. At least temporarily, producers obtained a price of from S/10 to S/15 per hundred pounds of crude salt, while the price of refined salt in Guyaquil dropped from S/5 to S/3 for a 5-pound bag.

Stone.—Many small localities in the Provinces of Loja, Azuay, Pichincha, Cotopaxi, and Napo-Pastaza yield onyx, travertine, diabase, and fossiliferous limestone for use as building stone.

Sulfur.—Small tonnages of high-cost sulfur have been produced more or less regularly to meet the domestic need of sugar refineries and Panama hat-makers. Production in recent years has been last reported from two volcanic deposits near the towns of Maldonado and Tufiño in Carchi Province.

MINERAL FUELS

Lignite.—The Azogue-Biblian lignite basin in Cañar Province is the most important in Ecuador and one that has been mined, albeit on a very small scale, entirely by hand methods. Production was expected to be increased in 1964 to supply fuel for the new Guapan cement plant. The reserves of Tertiary lignite have been estimated as 22.8 million tons in 5 minable seams of 0.6 to 1.1 meters thickness, ranging to depths of 250 to 500 meters below outcrops. The best bed is the Cañari, traceable for 14 kilometers along the strike. The beds include brilliant "black lignite"—possibly better classified as subbituminous coal—with calorific values from 3,600 to 4,600 kilogram-calories as mined and from 5,000 to 6,500 kilogram-calories when dried.

Two Tertiary lignite basins, Malacatos and Loja, are in the Province of Loja. The Malacatos basin has reserves of at least 3.3 million tons in two possibly workable seams. The Loja basin has considerable reserves in 5 seams regarded as workable and has supplied some brilliant lignite to local brick plants and rice mills.

The Nabón basin in Azuay Province has brilliant Miocene lignite in its Nabón and Palmira fields and Pleistocene lignite in its San Antonio field. Most of the beds are steeply tilted and not minable, and the lignite is high in sulfur. However, sink and float tests on some of the San Antonio coals gave a product suitable for thermal powerplants and for cement, lime, and brick kilns, and construction of coal washeries has been considered.

Digitized by Google

Petroleum.—The production of crude petroleum and natural gasoline has been declining steadily in Ecuador since the peak of 3,599,000 barrels was reached in 1955. Recently active producers in the Santa Elena Peninsula, west of Guayaquil, have been the Anglo-Ecuadorian Oilfields, Ltd., and its several subsidiaries, and Tennessee de Ecuador, S.A. (the Tennessee Gas Transmission Co.).[6] Past explorations in the Oriente region east of the Andes by the Shell Oil Co. (1939 to 1950) and of the Pacific coastal belt by International Petroleum Co. and the Standard Oil Co. of New Jersey were unproductive and abandoned.

Santa Elena crude, most of which comes from the Ancon field, is treated at three refineries. These include Anglo-Ecuadorian's La Libertad refinery which has a 12,200-barrel-per-day distilling capacity and a 6,000-barrel-per-day thermal cracking capacity; Anglo-Ecuadorian's new 6,600-barrel-per-day refinery; and Tennessee's Cautivo topping plant at its Tigre field which has a capacity of 2,500 barrels daily. Ecuador's requirements for refinery products are no longer met by domestic production, which has to be supplemented by imports.

[6] On January 1, 1964, Tennessee de Ecuador, S.A., officially became Cautivo Empresa Petrolera Ecuatoriana, C.A. owned 100 percent by Ecuadoran nationals.

The Mineral Industry of Paraguay

By Sumner M. Anderson [1]

PARAGUAY'S only active mineral industry in 1963 consisted of a cement plant and some limekilns with their supporting quarries, a rock-crushing plant, and the quantitatively unreported activities of three small glass plants manufacturing bottles and jugs and a few scattered brick and pottery kilns. Interest in the mineral industries was not dead, however. The rock-crushing plant is new and modern; cement production, which has been growing steadily, was seeking further expansion; petroleum exploration was resumed; construction was started on Paraguay's first petroleum refinery; and iron and manganese ore concessions were sought and granted.

Landlocked Paraguay is bisected by the Paraguay River which joins the Paraná and La Plata to give the country a 600 to 700 mile river route to the ocean. An international bridge over the Paraná River, unfinished in 1963, will link Paraguay with Brazil. The economy of the country depends almost entirely on products of the soil—agriculture, grazing, and forestry—and associated fields of manufacturing, commerce, communications, and services. In the 5-year period 1959–63, the gross national product (GNP) rose 36 percent to US$259 million (Guaranies 32,634 million, at 126.0 guaranies per U.S. dollar), population increased 9 percent to 1,857,000, and the GNP per capita in current prices increased 24 percent from US$112 to US$139.

Paraguay is poorly endowed in mineral resources and has not fully utilized what it has, although its plan for national development includes exploration of mineral industry expansion. An excellent basis for such studies, including a geological map, has been prepared by the U.S. Geological Survey, in cooperation with the Paraguayan Department of Geology [2], describing in some detail both the known limitations and many previously unrecognized potentials of Paraguay's mineral resources.

Paraguay does not export minerals. Imports, which have not been tabulated here, include all the country's requirement for minerals, metal and mineral manufactures (excepting the domestically produced cement, lime, and stone), and petroleum products (1,068 thousand barrels in 1962).

Data on production and recent mineral developments have been supplied by the U.S. Embassy, Asunción.

COMMODITY REVIEW

METALS

Iron.—During the latter half of 1963, a geological investigation of the feasibility of mining iron ore was started, reportedly under the sponsorship of the Economic Commission for Latin America and at the request of the Paraguayan Ministry of Defense. Particular attention was to be given to the surface-rich hematite-magnetite deposits of the Paso Pindó area about 8.5 kilometers north-northeast of Villa Florida. Small iron mines and foundries were last operated in 1870.

Manganese.—Three concessions for the exploitation of manganese ore were granted during the year to two Paraguayan nationals and one Argentine citizen. The concessions are in the Valle Yo'a area, Ita District, Department Central; the Yaguaron area, Department of Paraguarí; and the Colmena District, also in the Department of Paraguarí. No plans have been announced for working the deposits, and their commercial value has not been established.

NONMETALS

Cement.—The 18,500 metric tons of cement produced in 1963 was an alltime record high for Paraguay and the first close approach toward meeting the consumption needs of the country. Imports, which in the years 1958–61 averaged more than 3,500 tons annually, declined to less than 1,000 tons in 1962, and in 1963 were an estimated 500 tons.

Vallemí, S.A., a government-owned company, has operated the country's only cement plant located on the Paraguay River 536 kilometers north of Asunción, at Puerto Vallemí near Concepción, since 1952. The plant, employing the wet-grind, rotary-kiln process, was imported secondhand from Belgium and reconstructed by native labor under the training and supervision of a skilled German cement specialist. It is old and in need of modernization financing for which purpose a loan was being sought at the end of 1963 by the Ministry of Public Works and Communications.

Limestone and shale, abundant along this part of the Rio Paraguay, are quarried near the plant. Gypsum, the only other essential cement raw material, is imported from Argentina. Cement bags, grinding balls, and refractory brick also are imported. For fuel the plant uses pulverized charcoal, burned from timber cut in the company's 300 square kilometers of forest land. This charcoal doubtless represents

Digitized by Google

a substantial portion of the 12,000 tons reported as average annual production of the entire country.

Lime.—Some lime is imported from Argentina, but most of Paraguay's needs for the past century have been supplied by lime of rather poor quality from charcoal-fired kilns fed from small limestone quarries at Puerto Fonciere, Itapucumí, and several other places.

Stone.—The limestone used for the manufacture of cement and lime probably represents all that is produced in the country, although reserves are enormous and the acid soils of much of the farmland could be greatly improved by utilization of crushed limestone fertilizer.

Paraguay regularly produces unreported quantities of white and colored sandstone for walks, walls, and the exterior facing of buildings, and broken stone—mostly dark, fine-grained igneous rock—for street paving, rough wall construction, and foundations.

In March 1963, the Argentine firm of Petrominera, S.A., began operating its new US$1.1 million rock-crushing plant at San Antonio just south of Asunción on the east bank of the Paraguay River. The plant is equipped with United States machinery and has a capacity of 220 tons of crushed rock per hour. The firm contracted to supply 1.2 million tons of crushed rock over a period of a year and a half for construction of a highway (Route 11) to parallel the Paraguay River between Resistencia and Clorina.

No quarried stone in Paraguay is cut, polished, or elaborately dressed, but much is admirably suited for such treatment, including many fine marbles and granites.

MINERAL FUELS

Petroleum.—On February 4, 1963, a new contract was signed between the Paraguayan Ministry of Public Works and Communications and Petróleo Guaraní, S.A. (PEGASA), a subsidiary of the Brazilian firm of Fiduciaria Fluminense, S.A., to continue the "prospecting, exploration, and exploitation of hydrocarbons." Previous explorations under a similar contract signed in 1958 had produced no positive results. The period of activity specified under the new contract was 17 months from the date of the signing, and the area of exploration covered approximately 11,220 square kilometers in the southern part of the Chaco. If oil or gas is discovered, the area of exploitation is not to exceed 5,000 square kilometers. The Chaco region was explored for oil unsuccessfully by the Union Oil Co. in the 1940's and the Pure Oil Co. in the 1950's.

Refinería Paraguay, S.A., signed an agreement with the Paraguayan Government in July 1962 for construction of Paraguay's first oil refinery and a crude oil pipeline from Bolivia to Asunción. In September 1963, the Asunción press announced that the Fish engineering firm of Houston, Tex., had obtained the contract for the engineering plans for the refinery, to have a 10,000-barrel-per-day capacity to produce gasoline, kerosine, jet fuels, and diesel oil, and to be built on the Paraguay River 20 kilometers (12 miles) downstream from Asunción. Refinería Paraguay, S.A., is financed by Interfinancial Corp., of New York.

The Mineral Industry of Peru

By John Burgess,[1] Sumner M. Anderson,[2] and Lester R. Brown, Jr.[3]

MEASURED internationally on the basis of available world production data and estimates, Peru in 1963 supplied more than 1 percent of the total world production of 11 metal and mineral commodities as follows, in percent: Bismuth 19.1, silver 14.6, tellurium 8.4, lead mined 5.8 (primary lead smelted 3.3), zinc mined 5.3 (primary zinc smelted 1.6), barite 4.3, copper mined 3.7 (primary copper smelted 3.2), cadmium 1.5, antimony 1.3, iron ore 1.2, and mercury 1.1. Relative to the countries of the South American continent, Peru was the only producer of cadmium, selenium, and tellurium; the leading producer of white arsenic, bismuth, lead, zinc, mercury, silver, and barite; the second leading producer of antimony, copper, and gold; and the third leading producer of iron ore.

The Andean range in Peru is richly mineralized; it has been mined since earliest colonial days and before that by the Indians. The diversified mineral industries provide a livelihood for 14 percent of the population, surpassed only by the agriculture-and-fishing segment of the economy. Most of the metal mining, except for the Marcona iron ore operation, is conducted at altitudes ranging from 10,500 to 15,500 feet above sea level.

Indicators of the general economic progress of Peru are presented as follows:

	1959	1960	1961	1962	1963
Gross national product (millions of U.S. dollars)	1,602	1,896	2,062	2,411	2,706
Population (millions)	10.8	11.1	11.4	11.6	11.9
GNP per capita (dollars)	148	171	181	208	227
Cost of living index, Lima (1958=100)	113	122	131	139	148
Commodity trade:					
Exports, f.o.b. (millions of U.S. dollars)	312	430	494	540	540
Imports, c.i.f. do	293	373	468	537	556
Trade balance do	19	57	26	3	−16
Net foreign balance, inflow minus outflow do	39	−22	−7	29	60
Total mineral production do	242	294	320	349	387
Mineral production as percentage of GNP	15.1	15.5	15.5	14.5	14.3

The steady increase in mineral production, although impressive, has not kept pace with the growth in the GNP to which it has contributed on a scale that is high by any standard. Its ratio to the GNP is exceeded within Latin America only by those of Venezuela and Bolivia.

Digitized by Google

The distribution of principal values within the mineral industries in 1963 was as follows:

Commodity	Value, thousands of U.S. dollars	Percent of total mineral value	Percent of GNP
Metals:			
Copper	106,097	27.44	3.92
Silver	43,478	11.24	1.61
Iron ore	39,419	10.20	1.46
Lead	22,403	5.79	.83
Zinc	21,445	5.55	.79
Gold	3,195	.83	.12
Antimony	2,867	.74	.10
Bismuth	2,521	.65	.09
Molybdenum	1,436	.37	.05
Other	18,099	4.68	.67
Total	260,960	67.49	9.64
Nonmetals:			
Cement	15,926	4.12	0.59
Guano	5,727	1.48	.21
Salt	1,382	.36	.05
Sand and gravel	1,096	.28	.04
Other	4,398	1.14	.16
Total	28,529	7.38	1.05
Fuels:			
Petroleum and its products	95,000	24.57	3.51
Metallurgical coke	1,249	.32	.05
Coal	928	.24	.03
Total	97,177	25.13	3.59
Grand total	386,666	100.00	14.28

Most of the two score metals, minerals, and mineral fuels which comprise the materials of the industry are produced in excess of domestic consumption needs. In 1962 metal and mineral sales abroad accounted for 9.6 percent of the GNP and 40 percent of the earnings from total export sales. Peru was a net importer, however, of petroleum and its derivatives; in 1963 production of crude petroleum and natural gas liquids totaled 22,545,629 barrels against consumption by refineries and end-product users of 23,464,028 barrels.

The mineral industries and the Peruvian economy as a whole achieved substantial gains in 1963 despite the political uncertainties of an election year. Development capital continued to flow into the country in response to the exceptionally favorable investment environment presented by commercial and industrial laws successfully designed to stimulate economic progress.

SOURCE MATERIAL

Mineral production statistics are supplied by the Department of Mines, Division of Statistics and Economics, in its annual publication on the mineral industry (Anuario de la Industria Minera del Peru); the Mining Bank of Peru; and individual operating companies. The two latter sources also provide preliminary statistics on mineral exports, but the final official trade statistics, usually released a year later, are published in the annual Statistics of Foreign Trade (Estadistica

Digitized by Google

del Comercio Exterior) by the Superintendency of Customs, Ministry of Treasury and Commerce. These sources combine to give Peru the most comprehensive, detailed, and reliable statistical coverage of mineral activities of any country in Latin America. This basic information has been supplemented by general economic data from the Mining Bank of Peru, the Economic Data Book for Latin America prepared by the U.S. Agency for International Development, and the January 6, 1964, issue of International Commerce, U.S. Department of Commerce. Textual details have been gleaned from continuous field observations and conversations by the Minerals Attache and from articles and notes appearing in such trade and news media as the Engineering and Mining Journal, Mining and Metallurgy, The Mining World, The Mining Journal (London), Skilling's Mining Review, World Oil, The Peruvian Times, The New York Times, and Peruvian Report, by A. S. Lipsett (Brownsville, Tex.), 1963.

PRODUCTION

The metal production statistics presented in the accompanying production table may be regarded essentially as representing recoverable content in all forms. The Department of Mines, in reporting production, deducts from the fine metal content of ores and concentrates 5 percent for copper and lead; 10 percent for zinc, iron, manganese, molybdenum, and tungsten; 35 percent for arsenic, bismuth, cadmium, tin, etc., calculated in accordance with average recoverability experience.

TRADE

The declining trade balance, which reached an unfavorable position in 1963, has been primarily the result of increased imports of automobiles and heavy machinery and equipment, rather than any decline of exports. The United States is the principal buyer of Peruvian metal and mineral supplies. Other important customers include Belgium, The Netherlands, Sweden, France, Canada, Argentina, Brazil, Chile, Venezuela, India, and Israel. Peru is best known in international markets as a supplier of lead, zinc, copper, silver, iron ore, and bismuth, and a customer for iron and steel products, petroleum and its products, gold, and aluminum, in addition to manufactured goods. Complete details of 1963 trade are not expected before 1965; available details of mineral trade are tabulated herewith.

Total:				
Value of metal and mineral exports.				215,179,687
Value of all exports				540,039,326
Metals and minerals percent share in total exports.				39.8

[1] Converted from Peruvian soles at $/26.81/US$1.00.
[2] Data not available.
[3] Exclusive of 11,777 tons of bismuth ores to Japan, United States, and United Kingdom, valued at US$1,219,692, believed to have been intransit shipments from Bolivia.
[4] As officially reported. The obvious discrepancy between gross weight and lead content has not been explained or rectified.
[5] In addition 29 long tons of refined tin metal imported from Bolivia in 1961 and 7 long tons in 1962 were shipped to the United States. Peru has no tin refining facilities.
[6] Officially reported as tungsten content; however believed to be 60 percent WO_3 equivalent.
[7] Includes reexports.
[8] Less than 500 barrels.
[9] 97 thousand barrels in 1961 and 80 thousand barrels in 1962 to bunkers.

COMMODITY REVIEW

METALS

Antimony.—The largest single producer of antimony in Peru is the Cerro de Pasco Corp. at La Oroya which treats complex company-mined and custom ores primarily for their copper, lead, zinc, and silver values and recovers antimony as a principal byproduct. The La Oroya plant accounts for Peru's total production of antimony in the form of refined and mixed-metal bars. Other antimony districts producing ore or concentrates, partly for custom treatment at La Oroya and partly for Peru's export of antimony in those forms, include the Canta and Yauli districts in the Department of Lima, Huallanca in the Department of Ancash, Quiruvilca in the Department of Libertad, and Azángaro in the Department of Puno.

Arsenic Oxide.—White arsenic is an unavoidable rather than a willful byproduct of the La Oroya nonferrous metals refining complex. However, Cerro de Pasco has succeeded in transforming at least a substantial part of it from a liability to an asset by combining it with lime to produce a calcium arsenate insecticide. This product is particularly effective against the boll weevil and finds a good market with the Peruvian cotton growers; it is not an item of export. Production fluctuates principally in accordance with the amounts of enargite ($Cu_3As_5S_4$) in the copper ores smelted.

Copper.—In 1963 the Southern Peru Copper Corp., which at the start of operations in 1960 more than tripled Peru's mine output and quadrupled smelter production, extracted 118,295 tons of blister copper anodes at its Ilo smelter from 9,973,975 tons of 1.37 percent copper porphyry ore mined from the Toquepala open pits. The mine and concentrating plant are 87 kilometers northeast of the smelting center and port of Ilo, to which they are connected by a 167-kilometer standard gage railroad.

The Cerro de Pasco Corp. is Peru's second largest producer of copper and the largest integrated nonferrous metal producer. The

Digitized by Google

La Oroya metallurgical plant, 200 kilometers northeast of Lima, produced 36,913 tons of electrolytic copper, of which 63 percent was derived from complex ores supplied by its own five mines (Cerro de Pasco, Morococha, Casapalca, San Cristóbal, and Yauricocha) in the central Andean range and 37 percent from purchased ores and concentrates. Copper exports amounted to 34,231 tons valued at US$21 million, and local sales amounted to 1,325 tons valued at US$820,000.

In the last few years, the company has developed the McCune open pit at its Cerro de Pasco mine, stockpiling the low-grade copper ore for future treatment by heap leaching. In december 1963, an ore body of high direct-smelting grade was discovered in the pit. Rail shipment of this ore to La Oroya for smelting should raise the total metal production in 1964. The Yauricocha mine yields the company's only other direct smelting ore. The Cerro de Pasco, Morococha, and Casapalca mines have their own concentrating plants, and ores from the San Cristóbal mine are upgraded at the Mahr concentration mill. The Cerro de Pasco Corp. also owns bituminous coal mines at Goyllarisquizga and Jatunhuasi, and affiliated interests in Peru amounting to 60 percent of Minas de Cobriza, S.A. (copper mining), 60 percent of the Cía. Minera Raura, S.A. (lead-zinc-copper-gold-silver mining and milling), 46 percent of Industrias de Cobre, S.A. (electric wire and cable), 42 percent of Refractorios Peruanos, S.A. (refractory brick), 33.3 percent of Cía. de Minas Buenaventura, S.A. (lead-zinc-copper-silver mining and milling), 32.32 percent of Explosivos, S.A. (explosives), 28.54 percent of Metalurgía Peruana, S.A. (steel castings), and 22.25 percent of Southern Peru Copper Corp. Development of a 3 million ton vein-type deposit containing 3.5 percent copper continued at the Cobriza property 185 kilometers southeast of La Oroya in the Big Bend of the Mantaro River.

The Northern Peru Mining Co., a subsidiary of the American Smelting and Refining Company and the third largest copper producer in Peru, operated a mine, concentrating plant, and precipitation unit at Quiruvilca, 113 kilometers east of Trujillo. The company's 1963 production amounted to 5,719 tons of copper in concentrates and 712 tons in cement copper precipitated from acid mine waters. The parent American Smelting and Refining Company started an extensive drilling program on Peru's (and South America's) northernmost porphyry copper body at Michiquillay, 32 kilometers east of the city of Cajamarca. The contractors, Boyles Brothers of Salt Lake City, completed nearly 18,300 meters of diamond drilling in 1963 and are expected to continued throughout 1964.

The three leading companies accounted for 83.3 percent of Peru's mine production of copper in 1963, and 98.6 percent of the smelter products.

The French company Cie. des Minas de Huaron produced 12,156 tons of concentrates containing 3,386 tons of copper from its copper-lead-zinc mine 48 kilometers north of Cerro de Pasco.

The English-controlled Lampa Mining Co., produced matte containing 2,154 tons of copper from four small reverbatory furnaces near the Santa Lucia station on the Southern Peru Railway, 48 kilometers west of Lake Titicaca. The furnaces treated direct-smelting ore from the Berenguela mine and copper concentrates from the ore mined and

Digitized by Google

milled at the San Rafael mine. The company planned to close its smelter operation (the only British owned smelter in South America) and intensify its production of concentrates for shipment from San Rafael because of rising costs and declining ore grade at Berenguela. Experiments with a pilot segregation plant continued with varying degrees of success.

Peruvian companies producing copper concentrates included Minas de Cobre de Chapi, S.A.; Cía. Minera Pativilca, S.A.; Cobre Acarí, S.A.; Cía. Minera Algamarca, S.A.; and Cía. Minera Condor, S.A.

A Japanese company, Cía. Minera Condestable, S.A., resumed construction work on a 300-ton-per-day flotation mill at its mine near Mala, following settlement of difficulties in obtaining water rights. The mill was scheduled to go on stream in July 1964.

Gold and Silver.—The figures for total gold in the production table are those recorded in the official Anuario de la Industria Minera del Peru, and include an estimate of 100 kilograms (3,215 troy ounces) of fine gold produced annually by approximately 2,000 miners engaged in intermittent placer mining from streams on the eastern slope of the Andes. This product is not controlled by the Peruvian Government, and the actual yield is not known, but informed observers resident in Peru believe a more realistic figure is on the order of 700 kilograms. If such is the case, the official total figures may be short of reality by a well-rounded 19,000 to 20,000 ounces annually. In 1963 this unorganized placer production was augmented by a firm 4,609 ounces of gold dredged intermittently by the Natomas Company of Peru, formed by the Natomas Company of California and operating by agreement with the Sociedad Aurífera San Antonio de Poto, about 50 kilometers north of Lake Titicaca.

The only lode mine reporting production of gold exclusively in 1963 was that of the Andaray Gold Mines Co. in the Department of Arequipa which yielded 5,534 troy ounces. Cía. Aurifera Buldibuyo in La Libertad and the San Luis Gold Mines Co. in Ayacucho exhausted their commercial ores in 1962 and were shut down in 1962. The exclusively precious metal lode mines include Cía. Explotadora Millotingo (a major silver producer), Department of Lima, and Cía. de Minas del Peru, Department of Arequipa, which produce both gold and silver. All other gold and silver production was from a few precious metal mines with base metal byproducts and many base metal mines with precious metal byproducts or coproducts. Principally, but not entirely, the gold is associated with copper ores and the silver with lead and lead-zinc ores. Cerro de Pasco produced 39,459 ounces of refined gold (46 percent from purchased ores and concentrates) and 19,696,000 ounces of silver (58 percent from purchased ores and concentrates). The 118,295 tons of blister copper anodes produced by the Southern Peru Copper Corp. contained 1,268 ounces of gold and 80,860 ounces of silver. About mid-year the Consorcio Minero del Peru closed its Calpa and Otoca gold-silver-copper properties which ceased to be profitable, and merged with Cía. Minera San Juan de Lucanas in which it held 50 percent interest; the Consorcio was dissolved. The old San Juan de Lucanas mine was Peru's second largest silver producer, deriving 2,400,000 ounces from 155,000 tons of ore containing 17.8 ounces of silver and 0.032 ounce (1.01 grams) of gold

Digitized by Google

per ton and 1.05 percent lead. Other major silver producers were Castrovirreyna Metal Mines and Cía. de Minas Buenaventura.

Three new flotation mills for beneficiating silver ores were completed during the year: A 120-ton-per-day plant at the Machicala mine of Cía. Minera Acre, 40 kilometers (25 miles) east of Trujillo; a 50-ton-per-day plant at the Kiowa mine of Cía. Minera Yarabamba, south of Arequipa; and a 50-ton-per-day plant of the old Arcata mine of Cía. Minera Arcata, owned by Mauricio Hochschild and Peruvian associates, near Juli in the Department of Puno.

Iron Ore.—In addition to the 6,161,157 metric tons of iron ore reported as 1963 production, 1,340,820 tons was added to Marcona's crusher stockpile. Export earnings increased 13.2 percent over those of 1962, and Marcona supplied 25,930 tons of ore to the Chimbote steel plant.

The Marcona Mining Co. is the largest iron ore company on the west coast of South America, having a known ore reserve of over 400 million tons in a deposit on the coastal plateau about 336 kilometers (210 miles) south of Lima. The deposit is owned by the Santa Corporation, a semiautonomous Government agency which in 1952 entered into a leasing agreement for 20 years with the Utah Construction Co. and Cyprus Mines Co., who then formed the Marcona Mining Co. The lease was later extended for an additional 10 years. In the first 10-year period, Marcona maintained a uniform 60 to 61 percent shipping grade of iron ore by very selective open pit mining, concentration, and careful blending; the ore was shipped through its port facilities at San Juan Bay. In February 1960, a new agreement was concluded with the Santa Corp. which served as a basis for private ownership and construction of a beneficiation plant and port facilities at San Nicolas Bay, just north of San Juan Bay, at an estimated cost of US$55 million. The plant was designed to treat the primary magnetite ore which averages 58 percent iron with sulfur content up to 2.5 percent. This ore is ground, screened, and upgraded by magnetic separation, and a proportion of the product made into pellets containing 68 to 69 percent iron. The Lurgi pelletizing unit of the plant started operating in July 1963, and when two additional grinding and magnetic separation units are operating continuously, the plant will have a yearly capacity of 1 million tons of pellets.

The only other producer in the country was the Peruvian company Panamerican Commodities, S.A., which operates the Acarí iron ore mine 56 kilometers by paved road southeast of the port of San Juan. All mining was underground by sublevel stoping methods. In 1962 a dry magnetic separation unit was installed to upgrade the fines rejected by the crushing and sceening plant. The ore for export moves by truck to the company's port facilities just north of those of Marcona at San Juan Bay. Acarí production in 1963 amounted to 934,800 tons of ore averaging 64 percent iron. The ore reserve was reported to be sufficient for 2 to 3 years. Because of financial difficulties encountered in 1962, the Banco Minero was designated by the Government to oversee the operation until the Government's guarantee to the American Overseas Finance Corporation is repaid.

Iron and Steel.—The Chimbote plant of the Santa Corp. continued steel production at an uneconomic rate. The plant was in process of enlargement by the Santa Corp. which is heavily in debt.

Digitized by Google

Lead and Zinc.—In 1963 the metallurgical center of the Cerro de Pasco Corp. at La Oroya continued to be the largest producer of lead with 80,775 metric tons of 99.99 percent electrolytic lead, of which approximately 46 percent came from ores and concentrates purchased in the Central District. The center was the only Peruvian producer of refined zinc; the entire 53,905 metric tans of electrolytic slabs (99.99 percent zinc) came from Cerro's operating mines, in addition to which the company exported 90,000 tons of zinc concentrates averaging 56 percent zinc. The company's increase in production over that of 1962 can be attributed to (1) expansion of the lead refinery capacity from 168 to 200 million pounds per year; (2) expansion of the zinc refinery capacity from 110 to 126 million pounds per year; (3) increases in the market prices of lead, zinc, and silver; and (4) a year of compatible labor relations uninterrupted by strikes. By the end of the year, two new drainage tunnels being driven at Cerro de Pasco's Casapalca lead-zinc-silver-copper mine were open for 2 miles of the 7 miles needed to tap the veins below the lowest development workings at the 3,900-foot level. The volume of water encountered to the 2-mile point was 100,000 gallons per minute. Completion of the tunnel, which should greatly extend the life of the mine, lies several years in the future.

Other major producers of lead and zinc concentrates included Cía. Minera Atacocha, S.A. (the country's largest producer of lead from a single mine); Cía. Minerales Santander (a St. Joseph Lead Co. subsidiary and, next to the Cerro de Pasco Corp., the country's largest producer of zinc); the French Cie. des Mines de Huaron; Cía. Minera Milpo, S.A.; Sociedad Minera "El Brocal"; Northern Peru Mining Co. (American Smelting and Refining Company); Volcan Mines Co.; Sindicato Minera Rio Pallanga; Cía. Minera Santo Toribio, S.A.; and Sociedad Minera Yauli. Except as otherwise noted, these are Peruvian companies.

Since its creation in 1940, the Mining Bank of Peru (Banco Minero del Peru) has aided the development of the Peruvian mining industry by making loans to the small miners and sometimes to the larger Peruvian companies, selling equipment, tools, and explosives, purchasing ores and concentrates, and operating an assay office in Callao, seven branch offices, and five custom mills. The declining activities of the small miners are reflected in the custom mills, which treated 132,312 tons of ore in 1961, 94,243 tons in 1962, and 91,533 tons in 1963. As reported in terms of metal content, the ores milled in 1963 yielded 3,417 metric tons of lead concentrates, 3,373 tons of zinc concentrates, and 385 tons of copper concentrates. A local group, with a loan from the Mining Bank, was planning in 1963 to exploit the Chavin mine which Victor Kravchenko (author of "I Chose Freedom") sold to Ventures, Ltd., of Canada. The mine, 121 kilometers (75 miles) northeast of Chincha Alta, has an estimated 350,000 tons of high-grade lead-zinc ore.

For several years the Mining Bank has been trying to promote a lead smelter and zinc refinery to be located on the coast at Ancón, north of Callao, but recently decided that the lack of locally available coking coal would make operation of a lead smelter uneconomic. A revised proposal to construct a 100-tons-per-day electrolytic zinc plant

Digitized by Google

and an auxiliary 175-tons-per-day sulfuric acid plant has encountered little private support from the zinc mining companies.

Manganese.—Modest production of manganese ore has been entirely from the Gran Bretana mine in the Central District.

Mercury.—The Santa Barbara mine of Sociedad Minera El Brocal, S.A. (formerly operated by Fernandini, Clotel y Hermanos), near Huancavalica was the only producer of mercury in Peru in 1963. Its 3,086 flasks of liquid metal required the treatment of 65,160 metric tons of ore containing 3.6 pounds of mercury per metric ton.

Molybdenum.—A flotation circuit was installed in 1962 in the Toquepala concentrator of the Southern Peru Copper Corp. to recover the fractional percentage of molybdenum contained in the copper ores. This was Peru's only commercial source of molybdenum.

Tin.—A minute amount of tin in ores is recovered in lead-tin-antimony bars produced from lead drosses in the byproducts plant of the Cerro de Pasco Corp. at La Oroya. The only producer of tin concentrates, all of which is exported, was the Lampa Mining Co. which has added a tin concentrating unit to its copper concentrator at San Rafael.

Tungsten.—The low demand for tungsten has forced closure of all Peruvian producers except the Pasto Bueno mine of F. Malaga Santalla. Continued operation of this property at a reduced scale has been sustained only by the Peruvian Government suspension of the 4 percent export tax on tungsten ore. Cerro de Pasco plans to install a magnetic separator for the byproduct recovery of wolframite from ores at its Morococha mine.

Vanadium.—The Vanadium Corporation of America, which shipped a small cleanup tonnage of vanadium ore in 1962, closed down exploration in 1963 and disposed of all supplies and portable machinery. The corporation will maintain its old mining concession in the Mina Ragra District.

Byproducts.—In addition to its copper, lead, and zinc smelters and refineries, Cerro de Pasco conducts a complicated assembly of metallurgical operations at La Oroya to obtain the highest possible commercial yield from the complex ores it treats. These byproducts include the antimony, arsenic oxide, silver, and tin previously mentioned, plus bismuth, selenium, tellurium, copper sulfate, zinc sulfate, and much of the gold listed in the production table. Other items regularly produced but not reported quantitatively include sulfuric acid, calcium carbide, oxygen, hydrofluosilicic acid, silica brick, fire clay brick, magnesite brick, slag brick, and coke. Indium and thallium, now going to the dumps, can be recovered if and when justified by market demands.

NONMETALS

Barite.—This was the only nonmetallic mineral produced in Peru principally for export. The chief producers, Barmine Co. and Cía. Perfordora de Pozos para Irrigación, S.A., operated mines in the upper Rimac Valley, northeast of Lima. The barite was consigned to oil companies operating in the North American Gulf Coast, Chile, and Ecuador, for use in drilling muds.

Digitized by Google

Cement.—The cement manufacturers of Peru and their rated annual capacities are as follows:

Company:	*Capacity (metric tons)*
Cía. Peruana de Cemento Portland	612,000
Cía. Cemento Chilca	204,000
Cemento Chiclayo, S.A.	68,000
Cemento Pacasmayo	106,000
Cía. de Cemento Andino, S.A.	85,000
Total capacity	1,075,000

Production rose in 1963 to about 70 percent of rated capacity and may have met the requirements of the country, which previously has been a net importer of cement. To produce 754,089 tons of cement, the industry used 982,000 tons of limestone and 30,000 tons of gypsum.

Clays.—Most of the clay industry is small and well dispersed throughout the country. Refractarios Peruanos, S.A., continued to be the largest manufacturer of refractory brick, and the two largest copper companies are its best customers.

Lime.—Distribution of burnt lime produced in 1963 showed 45,000 tons consumed in construction, 22,000 tons for agricultural uses, 13,000 tons by mineral concentration plants, and 5,000 tons by chemical and industrial plants.

Phosphates and Potash.—Guano containing 14 percent nitrogen was the only phosphate fertilizer produced in 1963, as it has been for many years. In June 1963, the Cía. Administradora del Guano was absorbed by the Corporación Nacional de Fertilizantes (National Fertilizer Corp.), organized to increase the production and distribution of fertilizers.

The great phosphate rock reserves in the Sechura Desert, extensively explored since 1959 by Midespa Industries, Ltd., of Montreal, Canada, through its Minerales Industriales del Peru, S.A., remained unexploited throughout 1963. Minera Bayovar, S.A., was organized to mine the phosphate deposit with which potash and salt are associated. By special law the Congress granted Minera Bayovar exception to the monopoly control of salt production held by Estanco de la Sal, and also granted special consideration of a 7 cents-per-ton export tax and permission to export phosphate, potash, and salt on ships other than Peruvian registry. At the end of 1963 a contract between the government and Minera Bayovar awaited approval by the Ministry of Public Works and Finance.

Salt.—Production of salt fell short of domestic consumption by 16,254 tons in 1962 and 22,657 tons in 1963. Marine salt was produced by evaporation at the great Salera de Huacho, 25 kilometers south of the port of Huacho and about 5 meters below mean sea level. Solar evaporation also was used to crystallize salt from waters which leach the saline lands near the Hacienda Cantato, 7 kilometers from the port of Pisco, and from saline springs in both the coastal and sierra regions. Rock salt was mined from the 6-million-ton deposit at the Solera de Atacocha, 45 kilometers north of Ayacucho. All operations have been controlled by Estanco de la Sal.

The Morton Salt Co. and Rayon Peruana, S.A., have joined in founding a new company, Industrias Químicas del Peru, which in 1963

Digitized by Google

was engaged in the construction of a new electrochemical plant near Lima's satellite city of Ventanilla at a cost of about US$3.5 million. The plant was scheduled for operation in April 1964. Salt will be utilized to manufacture caustic soda and other chlorine derivatives at an initial rate (later to be increased) of 15 tons per day. This should greatly reduce the imports of caustic soda, which in 1963 amounted to 12,606 tons valued at US$797,000.

MINERAL FUELS

Coal and Coke.—Cía. Carbonera Pallasca, S.A., produced 13,370 tons of washed and sized anthracite in 1963 from its mine near the Santa River approximately 100 kilometers east of Chimbote. Paid up customhouse permits were issued for the export of 13,557 tons of anthracite from this mine to Japan. The Northern Peru Mining Co. produced 7,800 tons of anthracite from its Cuyacullo mine for heat and fuel in its camps. The only other anthracite production during the year was unreported quantities from small seams in various areas of the country for domestic use.

Cerro de Pasco mined 118,000 tons of bituminous coal from its Goyllarisquizga mine in the Department of Pasco, and produced 39,500 tons of metallurgical coke, all of which was used in the La Oroya smelter. The company also imported 500 tons of metallurgical coke from England and planned to import a similar tonnage in 1964.

Petroleum.—Peru's petroleum industry is long established but production has been relatively small, being outranked in South America by that of Venezuela, Argentina, Colombia, and Brazil. Nevertheless, in recent years it has accounted for over 4 percent of the gross national product and employed more than 9,000 people with an annual payroll of about US$25 million. The relationship between the characteristics of Peruvian petroleum and the pattern of domestic demands is such that Peru (judged by data available for 1961 and 1962) is a net importer of crude and a net exporter of petroleum refinery products. Domestic consumption of 23,464,000 barrels of petroleum products in 1963 exceeded total production by only 918,000 barrels. The 19.2 percent increase in production of crude over 1959–62 was exactly the same as that of the South American Continent, and 8.7 percent greater than that of the world as a whole. During the same period, Peru's production of refinery products increased 15.0 percent.

In 1963 nearly 90 percent of the domestic petroleum products were produced at the Talara refinery of the International Petroleum Co., the major portion being consumed within the country. The Empresa Petrolera Fiscal topping plant near Iquitos and the small batch refinery of Cía. de Petroleo Ganso Azul, Ltda. at Pucallpa supplied the needs of the Peruvian Amazon basin for gasoline, kerosine, and diesel oil. The new Conchan topping plant, constructed in 1961 on the Pan-American Highway 29 kilometers south of Lima, went on stream February 15, 1963. It is owned jointly by the Banco Popular (65 percent) and the Standard Oil Co. of California (35 percent). Technicians of the latter company manage the refinery, and marketing is handled by Petrolera Conchan, S.A., which is owned by Mariano I.

TABLE 5.—Distribution of crude petroleum production by zone and company
(42-gallon barrels)

Zone and company	Production		
	1961	1962	1963
Northwestern coastal and Continental Shelf zones:			
International Petroleum Company, Lobitos	8,813,827	9,488,800	8,893,016
International Petroleum Company (I.P.C.)	7,831,095	8,110,111	8,603,843
Empresa Petrolera Fiscal	968,596	1,381,313	2,048,192
Belco Petroleum Corporation	623,248	598,936	568,692
Peruvian Pacific Petroleum Company	91,690	176,631	74,152
Petrolera Amotape	42,104	25,970	20,215
Douglas Oil Company	7,862	----------	----------
Total	18,378,422	19,781,761	20,208,110
Eastern zone:			
Cía. Petrolera Ganso Azul	687,306	787,944	754,553
Cía. Pedro "El Oriente", S.A.	305,146	563,749	505,337
Total	992,452	1,351,693	1,259,890
Total Peru	19,370,874	21,133,454	21,468,000

Prado of the Banco Popular. Refinery feed during the remainder of the year was 1,530,000 barrels of crude obtained from Venezuela (Boscan) and the State owned Empresa Petrolera Fiscal in northwestern Peru. Products consisted of gasoline, kerosine, diesel, and fuel oil marketed in the Lima area. It is possible that initial difficulties of operation were responsible for the sharp rise in refinery losses noted on the production table.

An organic law promulgated in May 1963 authorized Empersa Petrolera Fiscal (EPF) to solicit international bids for construction of a refinery of 12,500-barrel-per-day-output capacity. After receiving these bids, the EPF board of directors in September declared them null and void because of technicalities and announced that new bids would be requested shortly. This had not materialized by the close of the year.

The prolonged legal dispute between the International Petroleum Co. (Standard Oil Co. of New Jersey affiliate) and the Government of Peru, still unresolved at the end of 1963, has an unusual and complex history. In 1826 ownership of the La Brea property and its pitch deposits near Talara on the north coast was transferred by the government of the new Republic to one Sr. Quintana in payment of a debt of 4,964 pesos incurred for supplies used in the war of independence from Spain, won by Peru at the Battle of Ayacucho on December 9, 1824. Subsequently the property and its mining rights passed through several private hands and was extended to encompass the Mancana estate, also on the pitch deposits, and the contiguous Pariña estate. In February 1888, Sr. Genero Helquero, who had acquired the property 10 years earlier, sold it to Herb Tweddle, an English oil promoter, who leased it to the London and Pacific Petroleum Co. Meanwhile, a law had been enacted requiring the filing of claims of 40 hectares each for petroleum and coal. In 1911 the Peruvian Government, by resolution of President Leguia, ordered exact measurement of the 41,614 claims comprising the property and payment of their surface taxes, but the British company claimed exemption. In 1918 the Peruvian Con-

Digitized by Google

gress, responding to diplomatic protests by the British minister to Peru, authorized the government to submit the tax claim to the International Court of Arbitration. Then in January 1922, they enacted Petroleum Law No. 4452 which declared all petroleum deposits to be property of the nation and assigned to the government the right to grant petroleum concessions against a 10 percent royalty plus certain surface rentals. In April 1922, the Court of Arbitration, meeting in Paris, ruled that the owners and lessees should pay US$1 million as settlement of all taxes claimed to have accrued before December 21, 1921, and should be exempt from further taxation until 1972, when the property should become subject to all taxes then valid. On the basis of this decision, the International Petroleum Co., in February 1924, purchased the property. The settlement was paid, but the extended exemption and ruling that the subsoil of the La Brea-Pariñas property belong to a private and foreign company rather than the nation was regarded by many Peruvians as interference in the national sovereignty, and the matter became a political issue. On October 31, 1963, the Peruvian Congress unanimously voted to invalidate the 1922 arbitration award signed by the British and Peruvian Governments, in a bill stating that the agreement violated pertinent legal requisites and therefore does not obligate Peru. The bill also cancelled previous congressional authorizations to submit the question to arbitration by international negotiations. At the same time, a bill was submitted to the senate by the executive which offered two alternatives: A new contract with the International Petroleum Co. under a modified tax status (which I.P.C. claimed would be 102 percent of profits, equivalent to "economic confiscation"), or transfer of I.P.C.'s properties and operations to Empresa Petrolera Fiscal, the Government-owned petroleum agency. In the senate it was recommended to refer the question back to the executive for either selection of one of the two alternatives or re-entry into negotiations with I.P.C. in an effort to reach an acceptable formula for settlement. Interest in the controversy has been based on both its importance to the petroleum industry and the repercussions which any settlement may have on the general investment climate. I.P.C.'s gross investment in Peru is estimated at US$193 million.

The Mineral Industry of Surinam

By Garn A. Rynearson [1]

BAUXITE mining, processing, and export continued to dominate Surinam's mineral industry during 1963, accounting for 99 percent of the value of all reported mineral production and 77 percent of the value of all exported commodities. Output of bauxite increased about 7 percent from that of 1962 to an alltime high of 3,482,142 metric tons, exceeding the previous record production reported for 1960 by some 27,000 tons but nearly 153,000 tons lower than the export record set in that year. The gain over 1962 output was largely a result of an industry strike in British Guiana which gave Surinam an opportunity to supply a larger than usual share of the Canadian market.

Surinam, formerly known as Netherlands Guiana or Dutch Guiana, has produced more bauxite than any other country in the world. The country has no facilities for converting its bauxite into alumina, metal, or aluminum chemicals, and all its output has been exported, either in a raw or a calcined form. Total output from 1922 through 1963 amounted to 60.5 million metric tons, representing nearly 16 percent of the world supply during that period. Surinam was the leading bauxite producer in 1941 and from 1947 until 1956, when its annual output was surpassed by that of Jamaica. Surinam then ranked second for 4 years and has ranked third behind the U.S.S.R. since 1959.

As bauxite output increased in other parts of the world, Surinam's share of the world market dwindled from a high of 27.9 percent in 1947 to 11.5 percent in 1963. The United States has received 93 percent of Surinam's bauxite exports, and a large part of the remainder has gone to Canada.

Aside from its eminence in bauxite, the country's mineral industry is extremely limited, even for a small underdeveloped nation. Relatively modest amounts of sand, gravel, and clay and small quantities of gold and several pegmatite minerals are produced more or less regularly. The country does not produce portland cement or lime, for calcareous rocks apparently do not occur or are very scarce in the readily accessible regions. Furthermore, no mineral fuels are produced, but the possibility of finding and developing offshore deposits of oil and gas appears promising. Chromite, iron, manganese, and tungsten ores, as well as platinum, diamonds, beryl, mica, and kyanite are known to occur in the country. Apparently none of these known occurrences were worthy of exploitation on a commercial scale under conditions existing in 1963.

Efforts to broaden the base of the mineral industry have been hampered by the geographic character of the country. Surinam has large areas of swamp in the lowland coastal region and most of the interior highlands are covered by dense forest. Access to the latter region is extremely difficult, and large areas have not been prospected or even surficially explored. In 1959, the Geological and Mining Service began an ambitious long-range geological exploration program, known as Operation Grasshopper, involving the use of aerial photogrammetric and geophysical surveys and photogeologic studies to delineate the most promising areas for investigation by ground survey crews based at seven airfields established at remote localities in the interior. As of 1963, the project was still in its early stages but had already disclosed large bauxite deposits and a new and possibly important occurrence of chromite.

Surinam offers a number of advantages that may be attractive to foreign investors, including political stability, encouragement of private enterprise, generous tax credits and certain exemptions from customs duties for new industries, low wage rates, and a relatively high level of education and literacy. These advantages are tempered by inadequate and costly transportation facilities and general inexperience of the labor force.

Surinam is an equal partner with the Netherlands and the Netherlands Antilles in the Kingdom of the Netherlands and is an associate member of the European Economic Community. The country is autonomous except for matters of defense and foreign affairs, which are under the jurisdiction of the kingdom. The local government is headed by a governor who is the appointed representative of the Dutch Sovereign. He is advised by an advisory council of five appointed by him. He also appoints a Council of Ministers with a minister-president, but its members are responsible to the popularly elected Legislative Council (Staten) of 21 members. The country is divided into eight administrative districts—the urban capital district of Paramaribo and the districts of Commewijne, Marowijne, Surinam, Saramacca, Coronie, Nickerie, and Brokopondo—supervised by civil commissioners responsible to the Minister of Internal Affairs. The Geological and Mining Service is a part of the Ministry of Development.

The population of the country is estimated to number about 320,000; more than one-third of the populace live in the capital city of Paramaribo. About half of the working force is engaged in agriculture and about 5 percent in mining and associated activities. Dutch is the official language but English is widely spoken, especially in Paramaribo. The currency used in Surinam is the Surinam florin (or guilder); the rate of exchange is Sur.f1.00=US$0.535.

Mining, agriculture, and forestry are the principal productive sectors of the Surinam economy. Mining contributes roughly one-third of the gross national product, whereas agriculture and forestry together account for about one-sixth. A considerable part of the government's revenue is derived from taxes, royalties, and fees levied on producers of bauxite and payment for services and other fees by firms that ship the bauxite.

SOURCE MATERIAL

Statistical data on mineral production are those reported by the U.S. Consulate General at Paramaribo and include figures obtained from both official and company sources. Foreign trade data are from monthly and annual publications of the General Bureau for Statistics of Surinam. Background material and information pertaining to the mineral industry are based in part on consular dispatches and in part on the following published sources:

1. Lubig, M. R. Bauxite in Surinam. U.S. Department of Commerce, World Trade in Commodities, v. 8, pt. 23, No. 5, April 1950, pp. 1–7.

PRODUCTION

The total value of mineral commodities produced in Surinam during 1963 amounted to approximately US$35.7 million, compared with US$33.2 million in 1962. Bauxite represented slightly more than 99 percent of these totals, and the contribution of all other minerals amounted to only US$252,000 in 1962 and US$292,000 in 1963. The quantity of bauxite produced in 1963 increased 7 percent over that of 1962, but its value increased only 4.5 percent because the total output included a larger proportion of the lower value metallurgical-grade bauxite. About 15 tons of cassiterite and columbite-tantalite concentrates were produced during 1962 or 1963 for export to the Netherlands. An estimate of their value has been included in the previously cited figures for 1963.

[1] Exports.
[2] Imports from Surinam by the Netherlands. The Netherlands also imported 11 tons of unspecified metallic ores from Surinam in 1963, most or all of which probably was cassiterite or columbite-tantalite or both.
[3] Revised figure, supersedes that given in commodity chapter, volume 1.

TRADE

Surinam's foreign trade increased sharply during 1963, but its composition and general pattern remained much the same as in the 2 preceding years. Total value of exports increased by US$3.7 million to US$46.0 million, while the value of imports increased by US $3.9 million to US$59.0 million.

Bauxite has been by far the most important of Surinam's relatively small number of export products and has customarily represented about 80 percent of the total value of all goods exported. In 1963, however, bauxite's dominance diminished a few percentage points as the aggregate of receipts for other commodities attained a record US$10.6 million, representing 23 percent of the total. Other than bauxite, the most valuable export commodities are wood products (plywood, particle board, and lumber) and rice.

As is the case in most underdeveloped countries, Surinam's economy depends heavily on imports of consumer and capital goods. In addition to considerable amounts of foodstuffs, the country has imported virtually all its requirements for metals, fuels, and machinery and other heavy manufactures as well as many of the raw materials it needs for use in agriculture, construction, and light manufacturing. In terms of value, mineral fuels and lubricants have represented more than half of all imports of metals and minerals. Semimanufactures of iron and steel and cement also were major import commodities.

The United States and the Netherlands have been Surinam's principal trading partners. The value of bauxite exports to the United States have exceeded the total value of all other exports to all countries; however, the Netherlands has generally received the largest share of exports other than bauxite. Imports from the United States normally exceed those from the Netherlands. The principal imports from the United States have been machinery and vehicles, flour, lubricants, tires and tubes, and woven fabrics. Most imports of raw or semimanufactured metals and nonmetals came from the Netherlands and other European countries, and most of the mineral fuel imports came from Trinidad and the Netherlands Antilles.

[3] Data incomplete.
[4] Less than 1 ton.
[5] Excluding LP gases and petroleum asphalt.
[6] May include some refinery asphalt.

COMMODITY REVIEW

METALS

Aluminum Ore.—Surinam's bauxite deposits are of two general types. The low-level type is found within about 30 miles of the coast along the southern edge of the coastal sediments near Moengo and Paranam in the northeastern part of the country. The deposits near Moengo and some of those near Paranam occur as blankets 10 to 20 feet thick on low hills with little or no overburden. Some of the deposits on the west side of the Surinam River in the Paranam area extend 50 feet below sea level and are overlain by as much as 80 feet of sediments. Most of the bauxite in these deposits is high-grade material and, after being crushed, washed, and dried, yields a product containing 55 to 62 percent alumina, 2 to 5 percent silica, less than 10 percent ferric oxide, and 2 to 3 percent titania. A product containing 85 to 90 percent alumina may be obtained by calcining the ore.

Digitized by Google

Undiscovered deposits of this type almost certainly occur along the westward extension of this same geologic-physiographic zone.

The high-level type has been found from 75 to 110 miles south of the coast in the Lely, Nassau, Hokahin, and Wientiwaai Mountains between the Marowijne and Surinam rivers in the eastern part of the country and in the northern part of the Bakhuis Mountains in the west-central part. The bauxite in these areas occurs as alumina enriched parts of residual laterites capping plateaus and hills some 1,000 to 2,000 feet above sea level. The iron content of the high-level deposits is high but the silica content usually is low. Some deposits have been explored but none have been worked.

Early in 1963 the Geological and Mining Service disclosed the preliminary results of its investigation of bauxite deposits in the Adampada-Kabalebo area of the Bakhuis Mountains of Nickerie District. Bauxite was discovered in the area in 1960 by a ground party checking an aeromagnetic anomaly. Subsequent explorations by the Service included the drilling of some 350 holes and the sampling of 10 selected bauxite areas scattered along a northeast-trending belt about 30 miles long. The aggregate reserve of the drilled areas has been estimated at 162 million tons of bauxite containing more than 45 percent of available alumina, including about 87 million tons containing more than 50 percent. Total reserves of these and other deposits in the area have been estimated to be in the order of 300 to 400 million tons, including some 150 million tons with more than 50 percent alumina.

The ore contains from 17 to 25 percent of Fe_2O_3, but ore with more than 50 percent Al_2O_3 usually has less than 3 percent SiO_2 and less than 3 percent TiO_2—often having less than 2 percent TiO_2. Average thickness of bauxite in the deposits ranges from 3 to 8 meters with a maximum of 20 meters. Thickness of overburden ranges up to 3.5 meters but averages about 1 meter. The largest of the deposits studied contains about 41.5 million tons of ore, of which about 19.3 million tons has more than 50 percent alumina.

The low-level deposits have been worked since 1922 when Surinam Bauxite Co. (Surinaamshe Bauxiet Maatschappij), a wholly owned subsidiary of Aluminum Company of America (Alcoa), began mining and exporting bauxite from deposits near Moengo. In 1937 the company expanded its operations and started mining ore from deposits in the vicinity of Paranam. Alcoa dissolved the old company in 1958 and organized Suriname Aluminum Co. (Suralco) to take its place. In 1942 N.V. Billiton Maatschappij, a Dutch concern, started mining and shipping bauxite from deposits at Onverdacht west of Paranam. Alcoa's subsidiaries and Billiton have been the only significant bauxite producers and were the only ones holding mining concessions as of the end of 1963.

Suralco has a far larger investment than Billiton in Surinam's bauxite industry. Since 1959 it has produced about 70 percent of the bauxite exported from the country. Approximately three-fourths of the company's output in recent years has been supplied by its operations in the Moengo area. The raw ore mined from deposits at Ricanau Hill is hauled 13 kilometers by rail to a mill at Kikus near Moengo for processing. Calcined abrasive-grade bauxite as well as

Digitized by Google

metallurgical- and chemical-grade bauxite is produced at Moengo. In addition, small amounts of especially high-grade bauxite are calcined for use in the refractory industry. Total capacity of the four calcining kilns at Moengo is 200,000 tons per year. After being crushed and dried or calcined, the processed bauxite is loaded into ore boats for the 96-mile trip to the Caribbean via the Cottica and Commewijne Rivers.

Because reserves of the Ricanau Hill deposits are nearly depleted, the company has been preparing unworked deposits at Adjoemakondre Hill to supply ore to the Moengo mill. Full-scale mining operations should begin at the new mine early in 1965.

Suralco's main operating installations in the Paranam area in 1963 included a washing plant, drying and calcining kilns, storage facilities, and a shiploading station on the west side of the Surinam River at Paranam about 20 river-miles south of Paramaribo. The company also operated a crushing and washing plant and a heavy-media separation plant (to remove iron-rich particles from low-grade ore) at Rorac about 5 miles downstream on the east side of the river. The Rorac product is barged to Paranam for further processing and shipment.

Early operations in the Paranam area were sustained by ores from Topibo Hill and other surface or near-surface deposits on the west side of the river; however, mines near Rorac have supplied the bulk of the ore in the last decade. These later will be worked out by early 1965, but by that time the company expects to have a new mine in production at the Onoribo IV deposit just west of Paranam. This ore body, which is approximately 2,200 feet wide and 4,000 feet long, lies 27 to 50 feet below sea level, and preparations for mining have involved dredging a new channel for a tidal river that flowed over the deposit, removing overburden by a cutter-suction dredge, and extensive dike, road, and bridge construction. The excavated area has been damned off and pumped out, and silt and other debris at the bottom will be removed during 1964. Another ore body, known as Onoribo II, is to be readied for mining by 1965 or 1966, and the small Onoribo III deposit will be developed later. The Onoribo I deposit is worked out.

Approximately 90 percent of Suralco's total bauxite output during 1959–63 was metallurgical grade, 6.5 percent was abrasive grade (calcined to 85 to 90 percent Al_2O_3 and less than 1 percent moisture), and a little less than 3 percent was chemical grade. In addition, the company produced small quanities of "calcined chemical" bauxite (for refractory uses) at Moengo, and in the latter part of 1963 began making a refractory-grade product at a new 50,000-ton supercalcining plant at Paranam. This plant encountered operational problems during 1963, and a small part of its output was insufficiently calcined to be marketed for refractory uses. These problems reportedly have been solved, and the company hopes to increase the quality and quantity of output in 1964.

The bauxite products produced at Moengo and Paranam are transported to the United States and other destinations by the Alcoa Steamship Co. in its own vessels as well as chartered vessels. Because of river bars and shallow coastal waters, large oceangoing vessels can be only partially loaded in Surinam and must complete their loads at

[1] Insufficiently calcined for refractory uses.
[2] Calcined chemical-grade bauxite produced for refractory uses.

a transfer station in Trinidad which is kept supplied by smaller vessels. This procedure also is employed for Billiton's shipments.

Good progress was made during 1963 on the dam and 150,000-kilowatt powerplant being constructed by Suralco at Affobakka on the Surinam River about 60 miles south of Paramaribo. Closing of the dam was scheduled for the early part of 1964, and it was anticipated that enough water may be impounded in the future 600-square-mile lake to begin power generation in 1965. Most of this power will be used by the new alumina plant and aluminum smelter that Suralco began constructing in 1963 about 2 miles from Paranam. The 60,000-metric-ton refinery and the first 220,000-metric-ton alumina unit should be completed in 1965. A similar second alumina unit is planned and a third may be added. The company hopes to start baking pots in October 1964 and to have the refinery in production by July 1965, providing power is available.

These projects are being undertaken as part of a 75-year agreement signed in 1958 by Suralco and the Government of Surinam. In the so-called Brokopondo Agreement Suralco agreed to finance, construct, and operate the dam and powerplant and to build the alumina and aluminum plants as well. The latter are to be the private property of the company whereas the dam and powerplant are to be turned over to the government in the year 2033. In the meantime, 80 million kilowatt-hours of energy per year is to be made available to Surinam at cost, but the bulk of the energy to be generated is reserved for Suralco's use in its own plants or enterprises. The terms of the agreement grant the company exclusive bauxite exploration rights on domain lands and priority rights on private lands in that part of Surinam north of the Fourth Parallel and east of the Surinam River. The company is allowed up to 10 years to select an area of 500,000 hectares for general exploration and up to 20 years to choose an area or areas totaling not more than 20,000 hectares for mining concessions. Suralco also is granted an option to participate in the possible development of a hydroelectric project on the Tapanahony River under terms similar to those applying to the Brokopondo project.

The Billiton bauxite operation is considerably less complex than Suralco's. The raw ore is crushed and washed at Onverdacht near the mining areas and then railed 4 miles to the drying kilns, dry storage bunkers, and loading station at Smalkalden near Paranam. The bulk of the company's output is metal-grade bauxite, and a large

Digitized by Google

part is shipped to the alumina plant of the Olin Mathieson Chemical Corp. in the United States. Billiton has concluded an agreement with Suralco whereby the latter will process Billiton bauxite in its new alumina plant. Billiton will take up to 130,000 tons of the annual alumina output. A part of this alumina will be sold in the United States and a part will be sent to the new aluminum plant, its parent company is planning to build at Delfzijl, the Netherlands.

Several other firms, including the Suriname Minerals Corp. (a subsidiary of Ormet Corp.), Harvey Aluminum, and Reynolds Metals Co., are interested in Surinam bauxite and have applied for exclusive exploration rights in areas west of the Surinam River. Action on these applications has been deferred until the government's Bauxite Advisory Commission completes a study and makes recommendations concerning policy for future development of the country's bauxite resources.

Columbite-Tantalite.—Small quantities of columbite-tantalite have been found in several of the pegmatites and in nearby eluvial deposits in the so-called northern pegmatite zone of northeastern Surinam. A few tons of concentrate was recovered during 1962 and/or 1963, but the known deposits apparently are of only minor importance.

Gold.—Alluvial gold occurs along many of the rivers and creeks in northern Surinam and a few lode-gold deposits are known as well. Most of the gold produced comes from placer deposits in the Lawa River area near the south-central part of the border with French Guiana, although some also is produced in areas along the Surinam and Saramacca rivers in the north central part of the country. Surinam's annual gold production, however, is far short of the local demand by jewelers, dentists, and others, which is estimated at about 8,000 ounces per year. Gold output reached a 20-year low in 1962, less than half the annual average of some 5,300 ounces, but recovered somewhat in 1963.

The most productive gold concessions are those of N. V. Sarakreek Goudvelden, a Dutch mining firm, in the Lawa River area near Benzdorf. Prior to 1963 the placers on the concessions were worked in part by the company, utilizing several small draglines and washing plants, and in part by individual lessors with little or no mechanical equipment. During 1963 a 4.5-foot bucket-line dredge owned by Northshore Goldfields, Ltd., an American-financed, Canadian-registered firm, began operating on a royalty basis on Sarakreek property along Rufin Creek. Introduction of dredging operations should result in a substantial increase in gold output from the area.

Tin.—A few tons of cassiterite concentrate was exported to the Netherlands in 1963. The source of this cassiterite was not reported, but it probably came from pegmatites or associated eluvial deposits in the Jorka Creek area in the northeastern part of the country, near the border with French Guiana. One cassiterite-bearing pegmatite in this area has been described as having an outcrop 150 meters long and a maximum width of 25 meters and containing cassiterite disseminated throughout the rock as well as some rich "nests." A grab sample of the disseminated material indicated a grade of 70 grams per cubic meter. The grade of nearby eluvial material was reported to range from 200 to 1,000 grams per cubic meter. Furthermore, samples of

Digitized by Google

cassiterite-bearing alluvial material in the Jorka Creek area and in the Patamacca Creek area to the northwest ranged in grade from a trace to 500 grams per cubic meter of gravel.

NONMETALS

Construction Materials.—Data on the overall production of sand, gravel, and clays in Surinam are not available. Sand and clay evidently are produced in sufficient quantity to satisfy most local needs and some sand is exported, principally to the Netherlands Antilles. Rock suitable for some construction purposes is not readily available in the coastal area so appreciable quantities of crushed rock and gravel are imported from Trinidad and the Netherlands Antilles. Clay brick and tile and concrete blocks are manufactured in Paramaribo; 1,316 cubic meters of brick was produced in 1962. Cement, lime, and refractory brick are imported.

The Surinam Government operates a quarry and crushing plant near Phedra on the Surinam River where it crushes gneiss to gravel and sand for use in civil construction projects. In recent years the Suriname Aluminum Co. has been an important, if not the largest, producer and consumer of sand and gravel; construction of its dam at Affobakka has required roughly 350,000 cubic yards of concrete aggregate.

Lithium Minerals (Amblygonite).—In the latter part of 1963 the N. V. Billiton Maatschappij announced it had mined out the last of the amblygonite in a pegmatite in the Jorka Creek area on the Lower Marowijne River. This was the only amblygonite-bearing pegmatite known in Surinam. From 1961 to 1963 it yielded 1,696 tons of mineral containing about 9 percent Li_2O. All of the amblygonite recovered has been exported to the Netherlands and West Germany.

MINERAL FUELS

Petroleum.—The Colmar Surinam Oil Co. (N. V. Colmar Surinaamse Olie Maatschappij) is the only firm holding a concession for oil exploration in Surinam. This company is controlled by Gulf States Land and Industries, Inc., a subsidiary of Webb and Knapp, Inc. Its concession in Surinam includes most of the belt of sediments along the coast and that part of the continental shelf to which Surinam may establish sovereign rights. (Colmar has conducted extensive geophysical surveys onshore and offshore for a number of years but had done no drilling as of the end of 1963. Offshore seismic surveys apparently have indicated that area holds the most promise for finding oil or gas as the company reportedly has scheduled exploratory drilling from a drilling ship during 1964. It also is reported that a French investment group, headed by France's Bureau de Recherches de Pétrole, will join Colmar in a consortium to develop any oil or gas that may be found.

The Mineral Industry of Uruguay

By Garn A. Rynearson[1]

URUGUAY'S overall output of mineral commodities declined somewhat during 1963, reflecting a continuation of the generally depressed state of the nation's economy. The decline in output was due largely to the low level of activity in the important construction industry, because the extractive sector of the country's small mineral industry is based almost entirely on the production of a few nonmetallic minerals, particularly construction materials. The position of both industries should improve considerably upon implementation of two new major highway projects to be financed by loans totaling US$22.6 million from the International Bank for Reconstruction and Development and a new housing program involving US$6 million in AID funds to be matched by government peso funds.

The Republic of Uruguay is essentially a pastoral country with an economy based primarily on the production of wool and meat products for export, and roughly 60 percent of its total area of 72,172 square miles is utilized for grazing. Manufacturing is of secondary importance, the principal industries being food processing, textiles, construction, beverages, chemicals, metallurgy, and petroleum refining. The latter three depend almost entirely on imported raw materials. Mining is of minor importance in Uruguay as the country is notably poor in mineral resources other than construction materials.

Despite its strong leaning toward a state welfare system, the Government encourages private enterprise in all sectors, and Uruguayan law does not discriminate against a business enterprise because of foreign participation or ownership. However, the State is a strong competitor in the mineral industry through its autonomous entity Administración Nacional de Combustibles, Alcohol y Portland (ANCAP). ANCAP operates the country's petroleum refinery and one of its three operating cement plants. A fourth cement plant being erected by ANCAP will give it almost 45 percent of total capacity.

PRODUCTION AND TRADE

Data on the value of mineral commodities produced in Uruguay are not available for 1963 or for previous years. However, it is evident that the total value of the country's cement output far exceeds that of all other mineral products of domestic origin. A rough estimate based on export price indicates a value on the order of US$9 million for cement produced in 1963 whereas the total value of all other nonmetals,

[1] Physical scientist, Division of International Activities.

Digitized by Google

excluding those used in cement, probably was on the order of US$1.5 million.

Statistical data on mineral production are those reported by the U.S. Embassy at Montevideo and include figures obtained from both official and company sources. Figures on petroleum products were furnished by ANCAP, those on gashouse coke by Cía. del Gas y Dique Seco, those on cement by the cement producers, and those on lime by ASINCAL, the local association of lime producers. Data on other commodities were supplied mostly by the Uruguayan Bureau of Mines.

No attempt has been made to tabulate mineral trade data which have not been made available in complete form beyond 1961. It is hoped that a more nearly current presentation will be possible in future reviews.

COMMODITY REVIEW

METALS

The only metalliferous ores of possible economic significance that are found in Uruguay are the low-grade iron ores and the manganese ores which occur in several of the eastern departments. These deposits remain virtually unexploited. Gold formerly was produced in small quantities in the northern part of the country but no production has been reported for more than 20 years. Known occurrences of arsenic, copper, lead, mercury, tin, and zinc minerals and of pyrite apparently are of no commercial importance. Except for scrap, all metal requirements are supplied by imports.

NONMETALS

Cement.—Uruguay has three cement plants in operation, and another was being constructed in 1963. Total capacity of the four plants will be about 540,000 metric tons per year. The largest plant is that of Cía. Uruguaya de Cemento Portland S.A. (Lone Star Cement Co.) at Montevideo which has four kilns with a total capacity of 272,000 tons. The bulk of this company's output is ordinary portland cement, but it also produces up to 15,000 tons of rapid hardening cement. Clay is obtained nearby but limestone is quarried near Minas in the Department of Lavalleja about 70 miles northeast of Montevideo.

Administración Nacional de Combustibles, Alcohol y Portland has a 120,000-ton plant for making ordinary portland cement at Minas and a similar plant at Paysandú in the Department of Paysandú should begin operations in 1964. ANCAP produced 121,408 tons in 1962.

Cía. Nacional de Cemento, S.A. has a 36,000-ton plant near Pan de Azucar in the Department of Maldonado about 70 miles east of Montevideo. In addition to ordinary portland cement, this company produces up to 7,000 tons of white portland cement.

Some Uruguayan cement is exported to Argentina, Paraguay, and Brazil to alleviate shortages in those countries. Argentina imported 2,072 metric tons in 1961 and 1,084 tons in 1962. Brazil imported 1,169 tons in 1962 and 6,375 tons in 1963. Brazil has granted tariff concessions on cement and ANCAP hopes to increase exports to Rio Grande do Sul during 1964.

Other.—Relatively large quantities of sand, gravel, and stone are produced for domestic use and for export principally to Argentina. Limestone also is produced in large quantities for the local manufacture of cement and lime, but gypsum must be imported. Clays, dolomite, feldspar, and glass sand are produced for refractory and ceramic uses; talc for paper, soap, and toiletries; and a little mica is mined and ground for use in cement and stucco work. The northern part of the country produces some ornamental agate and amethyst, mostly for export. The only other nonmetals produced more or less regularly are small amounts of barite and alum-bearing rock. Known occurrences of asbestos, borax, emery, and graphite are not exploited.

Digitized by Google

FUEL AND ENERGY

Uruguay is practically devoid of resources of mineral fuels. Small deposits of peat and low-grade coals are known but are not utilized on a commercial scale. No deposits of oil or gas have yet been found. Furthermore, the country's hydroelectric potential is strictly limited and its natural fuelwood supply is small. Fuel requirements are supplied largely by petroleum products, refined in the country from imported crude petroleum, supplemented by imports of coal, coke, and some finished petroleum products. Of all energy consumed in 1961, petroleum was the source of about 65 percent, hydroelectric power 20.5 percent, wood and vegetable fuels 9 percent, wind power 3.5 percent, and coal 2 percent.

The 51,000-barrel-per-day refinery at La Teja, Montevideo, operates on its own account and on contract, processing imported crude petroleum to supply products for internal distribution and bunkers and, to a minor extent, for export. From 50 to 65 percent of the crude petroleum processed annually since 1958 was imported by ANCAP and the remainder was imported by three private companies—Esso, Texaco, and Shell. All four participate in the distribution of finished products. The total value of crude petroleum imported during 1963 was US$20.6 million compared with US$24.5 million for 1962 and US$20.7 million for 1961.

Uruguay also imports some finished petroleum products. Such imports in 1963 and 1962 (in parentheses) included 34,000 (120,000) barrels of gasoline, 147,000 (135,000) barrels of kerosine, 253,000 (167,000) barrels of distillate fuel, and 10,000 (14,000) tons of lubricants. No residual fuel oil was reported in 1963, but 232,000 barrels were imported in 1962. Total value of these imports in 1963 was US$3.15 million compared with US$6.6 million in 1962. These figures are derived from data reported by the U.S. Embassy, giving the Banco de la República Oriental del Uruguay as the official source.

The Mineral Industry of Venezuela

By Sumner M. Anderson [1] and Lester R. Brown Jr. [2]

VENEZUELA is a major world petroleum producer and an important iron ore producer. Although petroleum production had maintained a steady rise during the period 1959–63, its portion of the total world supply dropped from 14.2 percent in 1959 to 12.5 percent in 1963, and Venezuela's second ranking position among the producing countries was lost to the U.S.S.R. In 1963 production was second to that of the United States in the Western Hemisphere.

Venezuela's iron ore production declined both quantitatively and proportionately from sixth largest producer with 4.0 percent of the world output in 1959 to 11th largest producer with 2.3 percent in 1963. It dropped below Brazil to second position in Latin America and fourth in the Western Hemisphere.

In international trade, Venezuela was the world's leading exporter of petroleum, contributing to the liquid fuel requirements of many countries. Most of its iron ore exports, representing the bulk of production, were shipped to the United States and lesser tonnages to Western Europe.

Output of the mineral industries of Venezuela, as measured by products and associated services, was valued in 1962 at US$2,542 million, equivalent to 44.70 percent of the gross national product of US$5,762 million. Although the country has a diversity of mineral resources, 95.87 percent of its mineral income was from the petroleum industry which employs only 2 percent of Venezuela's labor force. Distribution of the remaining 4.13 percent of the mineral economy shows, in U.S. dollar values, iron ore US$82.0 million (3.22 percent), cement US$18.6 million (0.73 percent), diamonds US$3.0 million (0.12 percent), gold US$1.0 million (0.04 percent), and salt US$560,000 (0.02 percent). Coal valued at $102,000 and limestone (other than that used for cement manufacture) valued at US$32,400 represented a combined contribution of less than 0.005 percent. Comparable data for 1963 have not been made available, but production statistics suggest that the relative percentage of the petroleum industry was up slightly at the expense of the other combined segments of mineral productivity. The trend in iron ore production, the country's second ranking export, has been downward since 1960.

The extraordinary mineral wealth of the country has been largely responsible for the regularly favorable foreign trade balance and the average 4.5 percent annual growth of the gross national product

Digitized by Google

during the years 1958–63. Other annual growth rate percentages in the same period were: Population 3.4; agricultural productivity 6.5; industrial productivity 8.0; crude petroleum output 4.4.

The dominant importance of the mineral industries domestically is as a provider of revenue and a basis for planned industrial development, increased employment, and economic advancement. In terms of 1963 resource utilization, Venezuela was self-sufficient or virtually so in petroleum products, natural gas, coal (other than metallurgical coking grade), cement and lime, common rock and minerals of construction, and salt, and partially self-sufficient in steel mill products. Small exploratory production of natural phosphate was started in 1963. All other metal and mineral products as well as manufactures were imported. Copper, manganese ore, mercury, nickel ore, asbestos, and magnesite have been produced in the past and may again be produced. Known unexploited resources include bauxite, chromite, pegmatite minerals, and sulfur. The largest and geologically most promising mining area of little or no mineral exploration is the Guayana Highlands, occupying the edge of the great Precambrian Brazilian shield south and east of the Orinoco in the State of Bolivar and the Territories of Delta Amacuro and Amazonas.

GOVERNMENT POLICIES AND PROGRAMS

Government efforts have been directed toward diversification of the economy, a more equitable distribution of land and income, improvement of education, housing, and social welfare, and a reduction of economic dependence on petroleum. An impressive program of public works included development of a national steel industry, a national petroleum organization, power projects, construction projects, and transportation facilities. In 1962 two large new bridges were opened to traffic, one over the Apure River at San Fernando and the other crossing the Aresting Channel, Margarita Island. A third bridge, completed in September, now spans the Lake Maracaibo strait, linking the growing city of Maracaibo and the western part of the State of Zulia with the main body of Venezuela east of the lake. Another bridge, started in December 1962 and scheduled for completion in about 3 years, will cross the Orinoco River near Ciudad Bolivar and provide access to the new steel plant and to a road being built into the Gran Sabana region of the State of Bolivar.

Perhaps the most imposing development plan is the multiphase project for the creation of a great industrial complex centering on the confluence of the Caroni River with the Orinoco River. The first phase of the project was the construction, a few kilometers upstream (south) of this point, of the Macagua Dam, begun in 1956 and completed in 1960. This dam entraps about half the flow of the Caroni River and feeds a 420,000-kilowatt-capacity powerplant. Actual output, reportedly ranging from 280,000 kilowatt in the dry season to 300,000 kilowatts in the wet season, supplies power to the Matanzas steel plant which has a reserve 6,000-kilowatt thermoelectric plant.

The second phase of the project was the Matanzas steel plant itself, wholly government-owned and officially named Division Siderúrgical del Orinoco, Corporación Venezolana do Guayana (CVG). Construc-

Digitized by Google

tion of this plant began in 1957 on the south bank of the Orinoco River, 17 kilometers (10.5 miles) west of the mouth of the Caroni River and near the ore docks of the Orinoco Mining Co. Production started from one train of its seamless-tube mill in mid-1961; from the first of its battery of eight electric smelting furnaces and its wire plant later in 1961; from two of its four open hearths, its rolling mills, and its merchant mill in 1962; and from the last of its open hearths and battery of smelting furnaces (including its one Strategic-Udy installation), another tube mill, and its foundry in 1963.

The third phase got underway in September 1963 with completion of negotiations with the International Bank for Reconstruction and Development (World Bank) for a US$85 million loan, to be matched by more than US$85 million of Venezuelan Government funds, for construction of one of the world's largest dams at Guri, 100 kilometers (about 60 miles) upstream from the mouth of the Caroni River. This dam would be capable of supporting a 6-million-kilowatt powerplant in addition to stabilizing the flow of water to the Macagua Dam downstream. The first phase of construction will require 5 years for completion. The industrial complex to be served by this combined power will be the new city of San Tomé de Guayana which will include the present towns of San Felix, Palua, Dalla Costa, and Puerto Ordaz, joined by a bridge being built across the Caroni River and encompassing the iron ore ports of the Orinoco Mining Co. and Iron Mines of Venezuela, the Matanzas steel plant, and an aluminum plant to be started jointly by the Venezuelan Government and Reynolds International. Feed for the aluminum plant will be imported alumina unless a successful conclusion of present research makes the treatment of imported bauxite by a new direct reduction process economically feasible. The population of the San Tomé de Guayana area increased from 4,000 in 1950 to 52,000 in 1963; it is expected to reach 140,000 by 1966 and possibly 250,000 by 1975.

To help implement and finance this social and economic reorientation, the government in late 1958 adopted a policy of granting no more petroleum or mining concessions and at the same time required the petroleum companies to pay royalties in advance, thus supporting the upward trend of the gross national product to a 1963 peak of US$6,201 million (US$737 per capita). However, these acts and other exactions from private enterprise generated a serious flight of both American and Venezuelan investment capital for the next 4 years; as public expenditures rose, private investment declined. The private direct investment was US$53 million in 1959, US$−145 million in 1960, US$−70 million in 1961, US$−184 million in 1962. Stoppage of the issuance of new petroleum concessions also decreased the amount of exploration and consequently the rate of development of petroleum reserves which remained at virtually the same level at the end of 1963 (17,013 million barrels) as they were at the end of 1959 (17,003 million barrels). During that period the ratio of production to reserves declined from 1:16.8 to 1:14.4.

SOURCE MATERIAL

Basic information on the mineral industry of Venezuela was derived from publications of the Ministry of Mines and Hydrocarbons (Ministerio de Minas e Hidrocarburos), including its Annual Report (Memoria) for 1961 and 1962, its Account of Activities (Informe sobre las actividades) for 1962 and 1963, and various issues of its Weekly Letter (Carta Semanal).

All foreign trade value data and quantitative statistics on all commodities, except petroleum, were prepared from the Bulletin of External Trade (Boletin de Commercio Exterior) for 1961 and 1962, published by the General Bureau of Statistics and National Census of the Ministry of Development (Direccion General de Estadistica y Censos Nacionales, Ministerio de Fomento). Quantitative data on petroleum foreign trade are from publications of the Ministry of Mines and Hydrocarbons.

Additional information on various aspects of the industry were obtained chiefly from the following sources:

Data on Petroleum and Economy of Venezuela. Creole Petroleum Corporation, Coordination and Supply Department, Caracas, July 1963.

Economic Developments in Venezuela, 1962. Overseas Business Reports, U.S. Department of Commerce, Bureau of International Commerce, Washington. OBR–63–73, March 1963.

PRODUCTION

The mineral potential of Venezuela is much more diverse than 1963 production which was limited to two metallic ores and their products, four basic nonmetallic minerals and their products, unrecorded quantities of construction materials, and three natural hydrocarbons and their derivatives. Production trends are upward in the hydrocarbons and cement, unprogressively steady to erratic in the other nonmetallic minerals, and sharply downward in the metallic ores.

TRADE

The dominance of the minerals industries—preponderantly petroleum—in the economy of Venezuela is reflected in the foreign trade pattern which regularly shows a strongly favorable balance. Exports exceeded imports in value by 4,511 million bolivars in 1961 and 4,769 million bolivars in 1962. Converting these figures to U.S. dollar equivalents requires the application of two exchange rates for exports and one for imports; during 1961 and 1962 the official free market rate was 4.58 bolivars per dollar and the petroleum export rate 3.09 bolivars per dollar. Using these factors, the favorable trade balance was equivalent to US$1,768 million in 1961 and US$1,894 million in 1962. Other dollar values are shown in table 2.

TABLE 2.—Exports and imports of mineral commodity groups

(Thousand U.S. dollars)

Commodity	Exports		Imports	
	1961	1962	1961	1962
Minerals:				
Metals	98,426	94,531	57,185	72,049
Nonmetals	3,706	5,640	4,134	4,020
Solid fuels			13	110
Petroleum and derivatives	2,408,132	2,607,692	6,427	6,826
Total	2,510,264	2,707,863	67,759	83,005
All other commodities	40,033	37,574	1,700,562	1,810,899
Total trade	2,550,297	2,745,437	1,768,321	1,893,904

Despite the relative subordinance of the nonpetroleum segments of the mineral-producing industries, they provide more than enough foreign exchange to pay for all Venezuela's import requirements for metals, minerals, and mineral fuels, exclusive of finished manufactures.

TABLE 3.—Exports of metals and minerals

(Metric tons unless otherwise specified)

COMMODITY REVIEW

METALS

Aluminum.—In April 1963 the Government announced that Aluminio del Caroni, owned 51 percent by its operating agency Corporación Venezolana de Fomento (CVF) and 49 percent by Reynolds Metal Co. of Richmond, Va., would start construction in July of a plant on the Caroni River to produce aluminum metal from alumina from the Reynolds plant at Corpus Christi, Tex., or from bauxite if research on a new direct reduction process proves successful. Under terms of the partnership, Reynolds will retain complete control of management. The plant will utilize power from the Guri Dam and power project and will have an initial annual capacity of 22,700 metric tons (25,000 short tons) to supply the requirements of Venezuela. Ultimately the installation will be doubled to produce metal for export. Further

Digitized by Google

expansion to treat Venezuelan bauxite will be considered if economic deposits are developed.

Imported aluminum billets and sheets, amounting to 7,000 to 9,000 tons annually in recent years, have been processed by four plants: Reynolds Aluminum Extrusions, Maracaibo, re-rolls coiled hot-rolled sheet to thinner sheet and foil and extrudes 6-inch billets to profiles; Aluminio Nacional, S.A. (an affiliate of Kaiser Aluminum and Chemical Corp.); Guacara, re-rolls sheet into foil; Corporación Venezolana de Aluminio (affiliated with Montecatini and Alcoa), Mariara, extrudes billets into profiles; and Alcan de Venezuela (an affiliate of Aluminium, Ltd.), La Victoria, re-rolls coiled cold-rolled sheets into corrugated sheets.

Gold.—Minas de Oro de El Callao, C.A. (MOCCA), a government entity, continued to operate a number of mines in the old El Callao area, State of Bolivar, primarily for employment of the local inhabitants who, for the most part, had no other means of livelihood. The steadily declining output accounted for about 96 percent of Venezuela's gold production in 1963, and all that came from underground mining. Three percent came from placer panning in open operation areas ("areas of free avail"), and 1 percent from placer mining in registered concessions.

Iron Ore.—Venezuelan iron ore has been produced in the State of Bolivar from both sides of the Caroni River south of the Orinoco by two companies: Orinoco Mining Co. (subsidiary of United States Steel Corp.), which began operations in 1954 at Cerro Bolivar and does its shipping from Puerto Ordaz on the Orinoco, and Iron Mines Co. of Venezuela (subsidiary of Bethlehem Steel Co.), which began operations in 1950 at El Pao and does its shipping from Palua also on the Orinoco. From the start of operations to the end of 1963, the Orinoco Mining Co. has mined 106.6 million metric tons of ore with a remaining reserve of 632.7 million tons, and the Iron Mines Co. of Venezuela has mined 31.1 million metric tons of ore with a remaining reserve of 99.5 million tons.

Recent operations have been as follows:

	Metric tons		
	1961	1962	1963
Orinoco Mining Co.:			
Production	12,430,996	10,532,113	10,038,305

Exported	14,561,365	13,309,792	12,353,701

[1] Approximately 95 percent of the ore sold in Venezuela goes to the División Siderúrgica del Orinoco (Matanzas steel plant) and the remainder to C.A. Venezolana de Cemento.

Digitized by Google

The downward trend in production since the peak year 1960 has been attributed to the general softening of the market internationally, to stiff competition from Canadian ores in the U.S. market, and to difficulty of the Venezuelan ores, which carry a fairly high percentage of fines, in meeting competition from beneficiated and pelletized ores. Factors adding to the somewhat accelerated decline in 1963 included a decrease in sales to the Matanzas steel plant and an interruption of exports by Iron Mines Co. of Venezuela when its transfer station at Puerto de Hierro on the Paria Peninsula reverted to the nation. On completion of new deep water loading facilities at Palua on the Orinoco River, Puerto de Hierro and its facilities became superfluous and were turned over to the Venezuelan Navy on November 1. To overcome competition in the export market, the Orinoco Mining Co. was considering a US$35 million to US$40 million investment in a plant to upgrade the present 60-percent iron content of its ore to 85 percent, utilizing natural gas from the East Venezuela oilfields and electric power to be generated at the Guri Dam. As planned, the plant would produce initially 1 million tons of enriched ore annually.

The Venezuelan Ministry of Mines and Hydrocarbons continued its exploratory survey of the San Isidro iron ore deposits south of Cerro Bolivar disclosing an ore reserve of 650 million tons with an average content of 60.17 percent iron. This is a government-reserve deposit destined eventually to supply the total ore requirements of the Matanzas steel plant.

The total Venezuelan iron ore reserve at the beginning of 1963 was estimated at over 2 billion metric tons with an average of 50 percent iron. Of this more than 1.3 billion was proved ore and the remainder probable ore.

Iron and Steel.—By the end of 1963, the Matanzas steel plant of the Corporación Venezolana de Guayana (CVG) was smelting iron ore and making pig iron, carbon steel ingots, blooms, slabs, billets, pipe, reinforcing bars, wire rods, wire, and structural shapes. The Strategic-Udy unit encountered three major difficulties during its intermittent 4 to 5 months trial runs: The ore driers were not ready for operation at the beginning of the rainy season, and an excessive burden was put on the kilns; the native coal from the Naricual mine failed to maintain its initially indicated specification of 5 percent ash and ran 20 percent ash, mostly in the form of clay, imposing an even greater burden on the kiln; and the hot-material-handling equipment proved incapable of withstanding continuous operation. The ore driers were finished and operative before the end of the year, but the trial runs were suspended pending installation of more durable hot-material-handling equipment and an effective quality control system at the Naricual mine, both of which were expected to be readied by mid-1964.

Aside from the Strategic-Udy furnace, the plant has eight Tysland Hole electric-arc furnaces, four Siemens-Martin open-hearth furnaces, and a foundry with two electric furnaces. A detailed description of the plant was published in 1959.[3] Dolomite and silica for fluxes are obtained locally; limestone is supplied from deposits on the Caribbean coast near Puerto La Cruz. Imported materials include about 100,000 tons per year of coke from England, 20,000 tons of manganese from

[3] Gonni, M. The Venezuelan Steel Works. Iron and Steel Eng., v. 34, No. 5, May 1959, pp. 71–93.

Digitized by Google

the Republic of South Africa, and 9,000 tons of ferroalloys—principally ferrosilicon—from European and U.S. sources.

Overall capacity of the plant, based on the nine primary furnaces operating in 1963, was 800,000 metric tons of pig iron per year, most of which was fed to the open-hearth furnaces and the foundry. The pig machine capacity was about 360,000 tons per year. Pig iron was sold to Japan and Italy in 1963, and steel billets were sold to the Ford Motor Co. in the United States. Annual capacities for iron and steel products include 295,000 tons of seamless pipe, 130,000 tons of structural shapes, 86,150 tons of reinforcing and merchant bars, 15,000 tons of barbed wire, 11,000 tons of plain and galvanized wire, and 1,200 tons of nails. Operations were expected to meet the needs of the petroleum industry for pipe, of the construction industry for structural shapes, and of the country as a whole for barbed wire. Venezuela was Latin America's second highest importer of tinplate with nearly 65,000 tons in 1962 and its highest per capita consumer (8.27 kilograms) but has not included tinplate in the short-term production expansion plans for its steel industry.

Aside from CVG and a few gray iron foundries making job castings and cast-iron pipe fittings, the iron and steel industry is represented by two private companies. Siderúrgica Venezolana, S.A. (SIVENSA), began full-scale operation of its plant in Caracas in 1954, feeding local scrap and iron ore mined locally to two electric-arc furnaces and producing merchant bar and reinforcing bar exclusively until 1962 when wire rod production was added. Ingot capacity is 75,000 tons per year and rolling-mill capacity about one-third higher. Rod production, amounting to 82,900 tons in 1962, has been consistently somewhat higher than ingot production which apparently is supplemented by purchases of ingot from abroad or from CVG or both. The company was planning a sizable program of diversification including facilities for making springs (which may have been installed and placed in operation during 1963), alloy steel bars and rods, and both ferrous and nonferrous castings. The other private company is Siderúrgica de Occidente, C.A. (SIDEROCA), near Maracaibo, which has been making about 12,000 tons per year of galvanized water pipe, ½-inch to 2-inch in diameter, from imported skelp.

NONMETALS

Cement and Gypsum.—Venezuelan cement was produced by the following four companies and seven plants controlled completely by Venezuelan capital:

	Plant location	
	City	*State*
Company:		
C. A. Venezolana de Cementos (VENCEMOS)	Pertigalete	Anzoategui
Do	Barquisimeto	Lara
Do	Maracaibo	Zulia
C. A. Fábrica Nacional de Cementos	La Vega	Federal District
C. A. Cemento Carabobo	Valencia	Carabobo
Cementos Coro C. A.	Coro	Falcon
C. A. Cementos de Táchira	San Cristobal	Táchira

Digitized by Google

Production started in 1909 with the plant at La Vega, a suburb of Caracas, and expanded to total self-sufficiency by about 1955. Output has been governed by local demand plus export marketability and has been far short of present capacity. The plant of VENCEMOS, inaugurated in 1949, located at Pertigalete on the Caribbean coast near Puerto La Cruz is the largest in the country with a capacity for producting 50,000 bags of cement a day. Its four kilns were fired by natural gas piped 97 kilometers (60 miles) from Anaco. Most of the other plants are fired by fuel oil, but the San Cristobal plant uses coal from its own company mine in Táchira.

VENCEMOS also operates Venezuela's only plaster plant with a 100-ton-per-day capacity at Pertigalete. Gypsum for calcining is transported by sea from the company's mine on the Paria Peninsula between Guiria and Puerto Hierro.

Diamond.—The exhaustion of certain rich diamond pockets worked in 1961 and 1962, coupled with an extended rainy season, accounted for the 60-percent drop in recorded production in 1963. The principal productive area for several years has been placers of the Paragua River and its tributaries in the Gran Sabana region of the State of Bolivar. The actual volume of production is obscured by the two-way contraband diamond traffic regularly operating across the Brazilian border. Official exports for 1963 showed 41,880 carats to the United States, 4,354 carats to England, 3,330 carats to France, and 19 carats to West Germany. The total 49,583 carats, comprised of both gems and industrial stones, was valued at only 6,362,542 bolivars (US$1,401,000).

MINERAL FUELS

Coal.—In a country abounding in petroleum and natural gas resources, coal has never figured prominently in the national economy. Between 1946 and 1963, most of the small production has been high-volatile bituminous coal from the State of Táchira. In 1961–62, 78 percent came from Cía. Minas de Carbon de Lobatera, owned by the government under the administration of the Corporación Venezolana de Fomento; 7 percent came from the captive mine of C. A. Cementos de Táchira; and 14 percent came from various small private mines within the State. Less than 1 percent was mined by C. A. Carbonera de Taguay in the State of Aragua. The coal was consumed by the local ceramic, cement, and brick industries.

Subbituminous coal and lignite at Naricual in the State of Anzoátegui was mined by the government until mid-1946 when it was closed down following a disastrous fire. Twelve years later, plans for the Matanzas steel plant revived interest in these coals for use in the iron smelting process, and an Interministerial Commission appointed by the Ministerio de Fomento and the Ministerio de Minas e Hydrocarburos rehabilitated and modernized the mine to a production capacity of 1,800 tons per day, rebuilt a railroad to the Caribbean port of Guanta, and remodeled docking and loading facilities. Most of this work was completed and shipments started by late 1962, but the coal was substandard for the use intended and corrective processing methods were being adopted during the latter part of 1963.

Petroleum.—Various aspects of the large and intricate petroleum industry reported in detail by the trade press are summarized by the tabulation of official data released by the Ministry of Mines and Hydrocarbons.

In conformity with official policy, no new concessions were granted in 1963, and President Leoni, inaugurated in March 1964, pledged himself to continue the oil policies of his predecessor. During 1963, the private companies returned 218,828 hectares, or 5.8 percent of the areas held at the end of 1962, to the Federal Reserve, and 1,200 hectares was assigned to the government-owned Venezuelan Petroleum Corporation (Corporación Venezolana del Petróleo).

In 1963, 503 new wells were completed (in 1962, 541), of which 5 were for the purpose of oilfield repressuring. Of the remaining 498 completions, 425 (85.3 percent) brought in new production. In the years 1959–62, increases in production of crude were general throughout the world but with some variations in growth rates: World total, 24.5 percent; Persian Gulf area, 34.0 percent; United States, 3.9 percent; South America (including Venezuela), 10.7 percent; and Venezuela, 15.5 percent. The Venezuelan trend continued upward in 1963 and is expected to continue upward again in 1964, but the rate comparison with other areas has not been calculated. Three of the private companies operating in Venezuela—Creole, Shell, and Mene Grande—accounted for 78 percent of the total production, 73 percent of the exports, and 85 percent of the refining in 1963, and they held 58 percent of the concessioned areas at the end of that year. Of the total production, 829,319,000 barrels had a gravity higher than 24.9 degrees API, 220,761,000 barrels had a gravity ranging from 24.9 to 14.0 degrees API, and 135,431,000 barrels had a gravity of less than 14.0 degrees API. Thirty-two percent of the petroleum produced was refined by 8 private companies and 1 government enterprise in plants in 13 localities. About 80 percent of the refinery products were exported excluding those refined in and exported from the Netherlands Antilles. There was an unexpected sharp increase in exports of both crude petroleum and fuel oils to Western Europe in 1962 and 1963 despite the maintenance of competitively high prices. This may be at least partly attributed to the unusually severe northern winter. Thirty-two privately owned depots distributed the remaining 20 percent of refinery products to industrial users and 1,631 service stations throughout the country.

The state-owned Venezuelan Petrochemical Institute (IVP) operated a fertilizer plant at Morón and has developed a growing export market for ammonia sulfate, superphosphates, and urea. Plans were studied to expand the petrochemical industry for the manufacture of synthetic rubber, plastics, detergents, chlorides, and caustic soda.

The Mineral Industry of Albania

By Bernadette C. Michalski [1] and K. P. Wang [2]

THE RAPID GROWTH of the small Albanian mineral industry in the 1950's began to taper off by 1961 and slackened sharply in 1963. The abandonment of Soviet and East European technical assistance programs in mid-1961 greatly affected Albania's mineral development, since four-fifths of all technical aid personnel were engaged in mineral activities. Chinese assistance apparently has not been able to fill the void. Overall mineral production increases during 1961–63 averaged 1 percent per year in value, as compared with 3 percent in 1959 and 5 percent in 1960.

Although by world standards Albanian mineral output, except for chromite, is insignificant, it is vital to the country's domestic economy. The mineral industry generated about 14 percent of the gross industrial product in 1962 and employed a notable share of the industrial labor force. In recent years, mineral products have provided about three-fifths of the country's exports by value. Chromite and iron-nickel ores together constituted from one-fourth to one-third of the total export value. In 1963, total trade turnover increased 12 percent over 1962.

PRODUCTION

Official Albanian mineral production statistics for 1963 were not available in time for inclusion in this chapter. Estimates based on available reports indicate that among major commodities, output levels of chromite, cement, and petroleum refinery products increased somewhat over those of 1962; coal output was about on a par with that of 1962, and nickel-iron ore production fell considerably short of anticipated goals and the 1962 output level.

Refined products [3]—do	339	369	385	[2] 450	[2] 450

[1] Calculated on the basis of officially reported percentage changes.
[2] Estimate.
[3] Includes: Gasoline—53,900 tons in 1960 and 55,700 tons in 1961; gas oil—67,700 tons in 1960 and 62,600 tons in 1961; and diesel fuel—2,000 tons in 1960 and 3,400 tons in 1961; distribution of balance of total for 1960 and 1961 as well as totals for 1959 and 1962–63 are not available.

TRADE

Although Albanian-Soviet political differences had the greatest impact on technical assistance programs, they also influenced trade patterns. Expanded trade with mainland China and with some Western European countries was the result. The Albanian-Italian trade agreement for 1963 called for a 50-percent increase in crude oil shipments from Albania to Italy, from 100,000 metric tons in 1962 to 150,000 tons in 1963. Other mineral products to be exported from Albania were natural asphalt, iron-nickel ore, and chromite. In exchange, petroleum products and chemicals were to be shipped from Italy. Total trade between Italy and Albania was about US$8 million as compared with US$5.6 million in 1961. Trade with mainland China has been steadily rising, whereas trade with other East European countries showed little change.

TABLE 2.—Exports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1960	1961	Principal destinations, 1961
Metals:			
Chromite	248,500	233,800	Czechoslovakia 62,900; Poland 55,200; East Germany 47,700; mainland China 36,600.

Mineral fuels: Coke	8,323	5,954	All from Poland.

COMMODITY REVIEW

METALS

Bauxite.—Geologic explorations in 1963 reportedly uncovered refractory-grade bauxite deposits at Lesh Rreth, Kaharig Mountains, Krirje, and in southern Albania. No plans for exploitation were announced.

Chromite.—Chromite output in 1963 represented about 7 percent of the world's total, ranking the country first in Eastern Europe and second to the Soviet Union in the Sino-Soviet bloc. Albania's output consists of 38 to 45 percent CR_2O_3 grade ore. Virtually all the chromite was exported, mainly to Eastern Europe but also to mainland China and (during 1963) to Italy. The principal producing area has been Bulquize; lesser areas include Tropoye Rreth, Kukesh, and Pogradec. Much geologic exploration was conducted in 1963, mostly around Martanesh, in the hope of uncovering new ore deposits.

Copper.—In view of the copper shortage of the Sino-Soviet bloc, development of Albania's small deposits has received emphasis in the technical assistance programs of both the U.S.S.R. and mainland China. The principal mining area in 1963 was Rubik, where a smelter is located. Exploitation of deposits at Kurbnesh proved disappointing; however, the smelter there was in operation, processing ores from other areas. Albania's two small copper smelters consumed coke made from Polish coals. The country's 1963 copper-output target reportedly was barely fulfilled.

Two new copper deposits showed promise. One is at Gjegjaj near Kukesh Rreth and was apparently discovered in 1961. No details are known about the ore body, but construction of a copper smelter was underway in 1963 with completion scheduled for 1964. Fuel for the new Kukesh Rreth smelter is to be supplied by the Stalin Town petroleum coke plant. The second deposit is at Puke Rreth, where ores are said to average 3 to 6 percent copper.

A copper refinery as well as chromite benefication facilities were reportedly under construction at Lac in 1961. These projects were to be completed by the Chinese after Czech assistance ended. No subsequent information has been available on the progress at Lac.

Iron-Nickel Ore.—Albania's many iron-nickel mines did not fare particularly well in 1963. The Albanian press reports that the industry attained less than 60 percent of the plan for the year. Most Albanian ore, which averages about 1 percent nickel, was shipped to Sered,

758-002—65——24

Digitized by Google

Czechoslovakia, where there is a 2,000-ton-per-annum nickel refinery, however, some ore was exported to Hungary and mainland China.

Albania's leading iron-nickel mine in recent years has been Pishkash. Other known producers are at Cervenake, Bushtrice, and Prenjas; a new operation was reportedly started at Prenjas in 1963. Geological exploration during 1962–63 uncovered additional prospects in Puke, Pogradec, and Leskovik. Hematite is the main iron constituent of Albania's iron-nickel ores, but there is also some magnetite. No geological and reserve information is available on these deposits.

Iron and Steel.—As of 1963 Albania had no steel industry. Despite the absence of coking coal and the limited known supply of iron ore, plans are underway to construct an iron and steel plant at Elbasan with Chinese assistance.

NONMETALS

Cement.—Albania was known to have three cement plants prior to 1963; namely, Vlore, Shkoder, and Tirana, which together produced 119,764 tons of cement in 1961. A fourth plant of unspecified capacity was reportedly completed in 1963 at Fush-Kruje.

Phosphate.—A phosphate mine was opened in Buloret in 1963. Construction of a superphosphate plant at an unspecified location was reportedly underway at the end of 1963.

MINERAL FUELS

Coal.—Albania's 1963 output of coal apparently barely reached the planned target. Most of the coal, comprising mainly lignite with some bituminous coal, came from Memaliaj, Krava, Alarup, Mborjedrenova, and Priska. Coal is produced for domestic consumption. Albania depends upon Polish coking coal for copper smelting.

Petroleum and Natural Gas.—Albania's oil and gas exploration program achieved some success in 1963, with the discovery of natural gas at Bubullime and Divjake and a new petroleum-bearing formation at Patos. In the same year, however, overall production by the petroleum industry fell short of target. Cerrick, Albania's largest refinery, was rated at 300,000 tons per annum, and Kucevo, the only other oil refinery, was rated at 150,000 tons.

ELECTRIC POWER

The country's electric power output of approximately 250 million kilowatt-hours in 1963 was not adequate to support the industrial program. Two new hydroelectric plants, Shkopet and Bistrice, were in various stages of planning and construction at the end of 1963.

The Mineral Industry of Austria

By Justin B. Gowen [1]

ALTHOUGH Austria's mineral output is not large on a world basis, the production of a few important mineral and metal commodities for export has more than compensated for the import of those which are in short domestic supply. A substantial exportable surplus has been regularly produced in aluminum, antimony ore, graphite, iron and steel, magnesite, and talc. Other minerals produced in quantities of major significance to the national economy include copper, lead, zinc, iron ore, kaolinite, bentonite and illite clays, salt, coal, and petroleum.

In 1963 Austria's gross national product was valued at US$7,665 million ($7,188 million in 1962), of which about 3 percent was contributed by mining and quarrying and 5 percent by iron and steel. While mine production of the nonferrous metals does not meet domestic requirements for metallurgical products, the iron and steel industry, with a marketable production value estimated at more than $400 million in 1962, is the most important sector of Austria's mineral economy.

The principal basic mineral industries as listed in 1962 included 126 mines and quarries, 5 salt mines, 1,178 producing petroleum and gas wells, 6 salt and 8 magnesite mines and processing works, 5 nonferrous metal reduction works, and 5 iron and steel works. These industries employed about 105,000 persons, or 17 percent of the industrial labor force and 4.4 percent of the country's total gainfully employed.

Most of the companies involved in the operation of these industries were government owned; nationalized enterprises were responsible for the production of all of the copper and lead-zinc ores, more than 99 percent of the iron ore and pig iron, 95 percent of the crude steel, more than 96 percent of the coal, about 85 percent of the aluminum, and 83 percent of the electric power. Employment in the nationalized industries, including chemical, manufacturing, and transportation sectors, was 130,320, or 21 percent of the industrially employed in 1962.

SOURCE MATERIAL

Statistical data were obtained from publications of the Ministry for Trade and Reconstruction—Supreme Mining Authority, The Austrian Central Statistical Office, The Austrian Länderbank, the Credit Bank Association, and Embassy dispatches.

PRODUCTION

Production in 1963 showed a substantial increase in the fuels and salt sectors; metallic ores decreased only slightly. However, the continued downward trend in nonmetals, led by magnesite, has apparently reduced the total value of mine and quarry products for 1963, shown in detail as follows:

Commodity sector	Value of production (million U.S. dollars)				
	1959	1960	1961	1962	1963 [1]
Petroleum and natural gas	66.3	73.8	71.9	74.2	78.0
Stone and industrial minerals	45.4	55.1	66.2	60.0	52.0
Coal	40.4	43.8	40.3	42.3	45.0
Metallic ores	30.5	34.6	33.5	34.3	34.0
Salt and brine	5.7	6.1	6.5	6.7	8.0
Total	188.3	213.4	218.4	217.5	217.0

[1] Estimate.

TRADE

Gross exports in 1962 were valued at $1,263.4 million, of which $350 million represented minerals and metals. Iron and steel products ($208 million), magnesite products ($48 million), and aluminum ($31 million) provided the bulk of the exports, more than 50 percent of which went to European Economic Community (EEC) countries, principally the Federal Republic of Germany. Communist countries took 19 percent and the European Free Trade Association (EFTA) took 14 percent. Mineral exports to the United States were valued at about $8 million with metals predominating.

Gross imports in 1962 were valued at $1,551.8 million. About $310 million comprised minerals and metals and their semifabricated products, exclusive of gold; solid fuels and energy accounted for $92

Digitized by Google

million, petroleum and products $54 million, iron and steel $51 million, nonferrous metals $36 million, metalliferous ores and scrap $31 million and industrial minerals and products $46 million. The EEC countries (mainly the Federal Republic of Germany) were the principal source of supply accounting for about 46 percent, followed by the East European Communist nations with 29 percent, and the EFTA nations with 7 percent. Mineral imports from the United States were valued at about $14 million and consisted principally of coal and unspecified metalliferous ores.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962

Refined unwrought	1,240	1,640	West Germany 1,405; Italy 183; Switzerland 52.
Alloys	107	[1] 733	West Germany 378; Italy 354.
Scrap	99	721	West Germany 396; Italy 215; Hungary 100.
Semimanufactures	4,901	4,423	U.S.S.R. 972; West Germany 558; Sweden 488; Switzerland 192; Netherlands 182.
Gold, bullion and semimanufactures	troy ounces	5,948	10,707	West Germany 8,648; Netherlands 739; United Kingdom 289; Switzerland 161; France 161; Hungary 161.
Iron and steel:			
Iron ore	thousand tons	10		
Roasted pyrites	do.	4	1	All to West Germany.
Scrap	do.	5	5	Switzerland 2; Belgium-Luxembourg 1; West Germany 1; Italy 1.
Pig iron and castings	do.	10	2	Italy 1.
Powder and sponge		76	116	West Germany 106.
Ferroalloys (all)		2,661	2,418	(2).
Steel:				
Ingots and semimanufactures for rerolling	thousand tons	432	442	West Germany 291; Italy 84; Belgium-Luxembourg 36.
Bars, rods, angles, shapes, and sections	do.	147	156	Switzerland 29; Italy 27; West Germany 16; Poland 14.
Hoop and strip	do.	25	46	Hungary 20; Switzerland 12; Czechoslovakia 4; Poland 4.
Plates and sheets	do.	528	531	West Germany 130; U.S.S.R. 86; Switzerland 76; Italy 53.
Other coated sheets	do.	10	9	Czechoslovakia 3.
Wire	do.	25	31	Yugoslavia 6; Hungary 6; Italy 6.
Railway track material	do.	21	29	Switzerland 22; Norway 2; Poland 1; Yugoslavia 1; Denmark 1.
Pipes tubes, and fittings [3]	do.	21	20	West Germany 4; East Germany 3; Poland 2; Switzerland 1; Hungary 1.
Lead:				
Ores and concentrates		22	6	All to West Germany.
Scrap		10		
Lead, unwrought		2,874	2,723	Italy 2,692.
Bars, rods, sections, and wire		1	1	(2).
Magnesium, all forms		188	235	West Germany 99; India 27; United Kingdom 22; Italy 18; Netherlands 17; Belgium-Luxembourg 16; France 12.

TABLE 2.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals—Continued			
Mercury—76-pound flasks	896	67	West Germany 58.
Molybdenum:			
Scrap—kilograms	17,416	18	All to West Germany.
Semimanufactures—do	245,813	126,100	United Kingdom 53,400; West Germany 19,200; United States 14,900.
Nickel:			
Scrap	151	134	West Germany 111; Switzerland 8; United Kingdom 11.
Semimanufactures	49	32	Czechoslovakia 9; West Germany 7; Yugoslavia 5; Bulgaria 4.
Platinum group, unwrought and semimanufactures—troy ounces	1,479	1,447	West Germany 579; Italy 547; United Kingdom 321.
Silver:			
Bullion—do	163,969	61,086	All to West Germany.
Other—do	96,452	102,882	Italy 51,441; West Germany 16,075; Yugoslavia 12,860.
Tantalum:			
Scrap—kilograms	400	300	All to West Germany.
Semimanufactures—do	2,200	1,700	Japan 1,000; West Germany 400; France 300.
Tin, all forms	106	16	All to West Germany.
Tungsten:			
Ores and concentrates	200	322	West Germany 302; United Kingdom 20.
Scrap	20	35	All to West Germany.
Semimanufactures	25	12	France 4; Italy 3; United States 2.
Zinc:			
Ores and concentrates	40	21	All to West Germany.
Scrap	60	86	Italy 45; West Germany 21; Yugoslavia 20.
Unwrought	5,096	3,689	Italy 2,977; Yugoslavia 560; West Germany 122.
Semimanufactures	22	7	Yugoslavia 4; Greece 2.
Nonmetals:			
Asbestos	342	233	West Germany 223.
Barite and witherite	30	----------	
Cement (hydraulic)	29,956	101,361	West Germany 55,864; Switzerland 45,475.
Chalk	1,262	2,870	Czechoslovakia 1,040; West Germany, 790; Italy 527.
Clays and refractories:			
Bentonite (not activated)	33	88	West Germany 42; Switzerland 40.
China clay (kaolin)	35,654	39,082	Italy 15,314; West Germany 9,764; Poland 7,703; Switzerland 6,039.
Fire and Dinas clays	52	58	Czechoslovakia 21; Switzerland 18.
Crude refractories	6,863	709	Italy 634; Switzerland 65.
Other refractories	27	24	Italy 21.
Corundum, artificial	5,798	9,530	(4).
Cryolite, natural	131	101	Italy 100.
Diatomite and other siliceous earths	179	103	Yugoslavia 26; Bulgaria 25; Switzerland 25.
Diamonds:			
Industrial—carats	(4)	----------	----------
Diamond and other gem stone powder.	(4)	----------	----------
Dolomite, unburnt, burnt, or sintered	15,067	14,799	West Germany 6,692; United Kingdom 2,944; France 1,140.
Feldspar	350	2,281	Czechoslovakia 1,980; Switzerland 300.
Graphite	20,018	18,226	West Germany 8,997; Italy 6,491; Yugoslavia 847.
Gypsum and anhydrite, crude or sintered.	34,362	39,867	West Germany 35,989; Switzerland 3,685.
Lime, burned, slaked, and hydraulic	209	237	West Germany 116; Turkey 80.
Limestone, industrial	18,500	----------	----------
Magnesite:			
Crude	603	773	West Germany 402; Italy 199; Switzerland 138.
Sintered	237,883	188,983	West Germany 76,033; United States 49,090; Italy 20,405; France 11,303; United Kingdom 11,025; Hungary 9,425.
Caustic calcined	97,026	96,600	West Germany 80,202; Italy 3,999; Czechoslovakia 3,279; Switzerland 3,071.
Magnesite brick	118,545	126,241	West Germany 30,445; France 17,987; Italy 11,638.
Chrome-magnesite products	137,311	108,655	France 22,704; West Germany 22,463; Italy 11,638.

TABLE 2.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Nonmetals—Continued			
Mica, including splittings and waste	5	5	All to West Germany.
Pigments, earth	2,118	2,290	West Germany 1,225; United Kingdom 468; Netherlands 233.
Pumice	1	3	(2).
Pyrites	18,579	3,988	All to West Germany.
Quartz and quartzite	2,379	101	Rumania 895.
Salt, including brine	1,394	2,469	West Germany 2,468.
Sand:			
Quartz	373	909	West Germany 799.
Other	28,149	20,266	West Germany 14,799; Switzerland 5,446.
Talc and soapstone	62,382	55,891	West Germany 19,881; Poland 14,521; Italy 5,472.
Vermiculite and mineral wool	70,924	93,000	West Germany 92,149; Italy 381; Switzerland 228.
Mineral fuels:			
Coal and briquets:			
Subbituminous and lignite. thousand tons	32	20	West Germany 19.
Coke do		10	All to Czechoslovakia.
High-temperature distillation products. do	3	4	West Germany 3.
Pitch and pitch coke do	4	1	(2).
Petroleum:			
Crude petroleum. thousand 42-gallon barrels	5,325		
Distillate fuel oil do	627	1,452	All to West Germany.
Residual fuel oil do	32	79	West Germany 34; Yugoslavia 11; Syria 11.
Asphalt do	5	16	West Germany 13.
Other do	4		
Electric energy millions kilowatt-hours	2,534	2,596	West Germany 2,278; Switzerland 211; Italy 107.

[1] Includes 125 tons of master alloys.
[2] Data not available.
[3] Does not include steel pipe with a wall thickness of more than 4.75 millimeters, or a diameter of 114 millimeters or more. Data on these sizes are not published.
[4] Less than 2,500 carats.

TABLE 3.—Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals:			
Aluminum:			
Bauxite	18,468	13,159	(1).
Alumina and aluminum hydroxide	161,541	142,473	(1).
Metals and alloys, unwrought and scrap.	387	868	Hungary 33; West Germany 16; Czechoslovakia 624.
Metal, semimanufactures	1,491	1,916	West Germany 848; Switzerland 565; Yugoslavia 154; Netherlands 117.
Antimony metal, all forms	153	146	Belgium-Luxembourg 115; West Germany 20; Netherlands 11.
Arsenic, white	33	33	East Germany 20; West Germany 13.
Cadmium:			
Unwrought and scrap kilograms	10,300	4,300	All from Belgium-Luxembourg.
Semimanufactures do	12,600	8,400	West Germany 6,400; Belgium-Luxembourg 1,000; Netherlands 1,000.
Chromite	83,377	62,539	Philippines 30,072; Turkey 22,919; Iran 6,280; Cyprus 3,184.
Copper:			
Ores and concentrates	550	506	All from Italy.
Blister	5,325	4,894	Republic of South Africa 3,963; Central Africa Federation 506; Italy 258; West Germany 132.
Refined unwrought	20,583	17,347	West Germany 15,561; Chile 813; Central Africa Federation 371.
Alloys	106	131	West Germany 86; United States 24.
Scrap	2,694	2,640	West Germany 848; United States 809; Netherlands 527.

COMMODITY REVIEW

METALS

Aluminum.—The record-high production of aluminum in 1963 was due in part to increases in productive capacity during 1961 and 1962 and in part to favorable hydropower conditions which permitted a greater utilization of available capacity. Austria has two primary aluminum producers, both of which have undergone modernization and expansion during recent years. However, production at times has been limited by seasonal shortages in the power supply.

The Vereinigte Metallwerke Ranshofen-Berndorf is state owned and had a rated capacity of 68,000 tons of primary aluminum at the end of 1962. The Salzburger Aluminumgesellschaft m.b.H. is a wholly owned subsidiary of the Swiss Aluminum G.m.b.H. (Alusuisse) with works at Lend in Salzburg. Capacity was recently increased from 7,000 tons to 10,000 tons of primary aluminum annually.

Copper.—The Mitterberg mine of the nationalized Kupferbergbau Mitterberg GmbH at Muhlbach (Salzburg) was the sole producer of copper ores and concentrates. The concentrates were roasted at Gailitz, and smelted and refined by the Montanwerke Brixlegg GmbH at their Brixlegg (Tyrol) works where the 500th anniversary of the copper smelter was celebrated in October. Improvements and additions to the residues preparation and anode casting plants raised the annual capacity of the electrolytic copper refinery to about 13,000 tons annually. Current annual requirements for refined copper and copper alloys are estimated at 35,000 tons.

Iron and Steel.—During 1963 the Austrian iron and steel industry attained a capacity of about 3.8 million tons of crude steel annually; pig iron capacity remained at 2.4 million tons. Production by type is shown in table 4.

TABLE 4.—Crude steel production, by type

(Thousand metric tons)

Year	Open hearth	Electric	L-D	Total	Year	Open hearth	Electric	L-D	Total

1958	907	321	1,165	2,393					

[1] Data not available.

Since the development of the Linz-Donawitz (L-D) oxygen-blast steelmaking process and installation of the first production unit at Linz-Donau in 1952, L-D steel has assumed increasing importance in the Austrian iron and steel industry, accounting for nearly 62 percent of the crude steel output in 1962.

Possession of the licensing rights and the technical knowledge relating to the process has contributed to the high development of the Austrian industry and its export capability.

Digitized by Google

In mid-1963 there were in operation throughout the world a total of 50 L–D plants with a combined capacity of 37 million tons of crude steel, and an additional 40 with a combined capacity of 35 million tons were either under construction or being planned. The latter include a plant with a capacity of 2 million tons annually for the U.S.S.R.

Of the country's five major primary steel-producing enterprises (including consolidations), four are nationalized. The two largest—Vereinigte Oesterreichische Eisen-und Stahlwerke A.G. (VÖEST) with main works at Linz-Donau, and the Oesterreichisch-Alpine Montangesellschaft with main works at Donawitz—are integrated with blast furnaces, rolling mills, and metal fabrication plants and are jointly responsible for the development of the L–D process. These two enterprises account for 99.5 percent of the country's pig iron (VÖEST 68.5 percent) and all of the L–D steel (VÖEST 78.4 percent); Alpine-Montan accounts for all of the iron ore production.

In mid-1963 VÖEST had a reported capacity of 2 million tons of crude steel. Preliminary production figures for the year credited the enterprise with an output of 1.7 million tons of crude steel (1.73 million tons in 1962) and 1.2 million tons of sheets (1.21 million tons in 1962). Sales reached a new high of $223 million, of which 61.4 percent was in exports.

Gebruder Böhler Aktiengesellschaft, with a crude steel capacity of about 190,000 tons, and Schoeller-Bleckmann with 86,000 tons, both nationalized, specialize in high-grade steels and steel products. Felten Guilleaume Fabrik Elektrischer Kabel, Stahl-und Kupferwerke A.G., with a capacity of 100,000 tons of open-hearth steel, is a subsidiary of Acieries Réunies de Burbach-Eich-Dudelange S.A. ARBED in Belgium.

Lead and Zinc.—The Government owned Bleiberger Bergwerks-Union operating the Bleiberg mine in the ancient Bleiberg-Kreuth mining district in Carinthia continued to be the country's only producer of lead and zinc ores and concentrates. The company's lead smelter (capacity 14,000 tons refined lead annually) and electrolytic zinc plant (capacity 13,000 tons annually) at Gailitz, near Arnoldstein (Carinthia) accounted for the total output of refined lead, electrolytic zinc and electrolytic cadmium. Imported concentrates from the nearby Raibl mine in Italy were treated at Gailitz on contract. Austria's current requirements were reported to amount to approximately 20,000 tons of lead and 15,000 tons of zinc annually.

The Gailitz lead smelter uses a direct smelting process, largely of their own development, which utilizes a rotary ore hearth to smelt a pelletized mixture of lead oxide and sulfide concentrates and residues. About 80 percent of the lead content is recovered as bullion. Slag from the ore hearth is retreated in a rotary furnace for recovery of the remaining lead.

NONMETALS

Graphite.—During 1962 four new graphite mines were added to the two—Zettlitz and Trandorf—already operated in Lower Austria by Prysok and Co. KG. The Trandorf mine was converted from an open pit to an underground operation, while a flotation plant and additional grinding facilities were added to the surface plant. During 1962 the

Digitized by Google

company produced 65,388 tons of crude graphite, making it Western Europe's leading graphite producer.

The Kaisersberg graphite mine at Franz Mayr-Melnhof & Co. in Styria produced 21,421 tons, mainly for export; the Mühldorfer Grafitbergbau A.G., produced 2,523 tons.

Magnesite.—The U.S.-owned Oesterreich-Amerikanische Magnesit Aktiengesellschaft Radenthein remained Austria's leading magnesite producer in 1963. During 1962 this company produced 958,500 tons, or 58 percent of the country's output, of crude magnesite. The other producing companies were the Veitscher Magnesitwerke A.G. which accounted for 599,600 tons, or 37 percent of the 1962 total, the Steirische Magnesit Industrie A.G. with 64,000 tons (4 percent), and the Oestereichisch-Alpine Montangesellschaft with 14,900 tons (about 1 percent).

The decrease in production and exports of magnesite and magnesite products since 1961 is attributed to the general decline in Western steel production, and to the increase in L–D oxygen converter steel relative to open hearth and other types. The steel industry is a major consumer of magnesite and magnesite refractories, but the L–D process is reportedly less dependent on the high-grade magnesite, because it can utilize a greater proportion of cheaper refractories, such as dolomite.

MINERAL FUELS

Coal.—Less than 2 percent of Austria's coal production was bituminous coal suitable for coking. The remainder consisted of lignite (82 percent) and subbituminous coal (16 percent), all of which was consumed in approximately equal proportions in power generation, industry, and households. The 1962 production of 5.8 million tons was derived from 29 mines; 14 of these, accounting for 96 percent of the total were operated by 7 nationalized enterprises.

The Grünbach mine was the principal producer of bituminous coal.

Based on 1956 estimates and subsequent mining, the reserve of bituminous coal and lignite at the end of 1962 was estimated at about 250 million tons of which 2 million tons was coking coal.

TABLE 5.—Coal production, by company, in 1962

sumption during 1961 and 1962 by principal consumer groups was as follows:

	Thousand metric tons 1961	1962
Coke ovens	2,154	2,119
Gas works	288	418
Powerplants	63	76
Transportation	540	552
Industry	311	273
Household	243	328
At mines	4	4
Total	3,603	3,770
From imports	3,496	3,671

Petroleum.—During 1962 somewhat more than a quarter of Austria's total energy requirement, estimated at 19.2 million tons of standard coal equivalent, was supplied by petroleum and petroleum products; 70 percent of these was from domestic production of petroleum and natural gas. The three producing companies were—

1. The nationalized Oesterreische Mineralölverwalting Aktiengesellschaft, which accounted for 91 percent of the 1962 crude production.
2. Rohöl-Gewinnungs A.G., owned 50 percent each by the Mobiloil and Shell companies, which accounted for 8 percent.
3. Tiefbohrunternehmen Richard K. van Sickle, which accounted for 1 percent.

Reserves in December 1963 were estimated at 268.5 million barrels of crude oil and 31.5 billion cubic meters of natural gas.

On December 23, 1963, Austria made the last oil delivery arranged under the terms of the Moscow Memorandum of April 15, 1955, and the State Treaty of 1955 as compensation to the Soviet Union for the return to Austria of former German oil properties located in the former Soviet-occupied zone. Under the original terms of the oil agreement, which was to expire in 1965, Austria was to ship 1 million tons of crude oil per year to the Soviet Union for 10 years. The agreement was amended in 1960 following the visit of premier Khrushchev to Vienna. At that time the quantity of oil to be delivered was reduced to 0.5 million tons per year and the shipment for 1965 was canceled. In all, 7.5 million tons of crude oil priced at about $103 million was delivered under the terms of the amended agreement which was to expire on January 27, 1964.

The Mineral Industry of Belgium

By L. Nahai[1]

BELGIUM continued to be an important processor of ores, concentrates and metals and a metal supplier in world markets in 1963. The country produces iron and steel, copper, lead, tin, zinc, cobalt, cadmium, silicon, germanium, uranium, and radium from imported ores and concentrates and crude metals.

Except for coal certain quarry products (sand, and gravel, various dimension stones, and crushed rock) and a small iron ore reserve, Belgium has no economic mineral deposits. The country is self-sufficient in the pit and quarry products mentioned above (except for sand) and produces much of the coal needed by the economy.

Although Belgium's production of iron and steel is only about 2 percent of the world's output, the Belgium-Luxembourg Economic Union is the world's foremost exporter of iron and steel. In 1962 Belgium ranked fifth in production of smelter zinc, accounting for 6 percent of the world's output. Its cadmium exports also were equivalent to about 6 percent of world production.

The gross national product of Belgium, at current prices in 1962, was $12.74 billion. The extractive industry contributed $274 million (2 percent), the iron and steel industry $358 million (2.8 percent), and the petroleum-refining industry $36 million (0.3 percent). In addition, $226 million was contributed by the fired-clay products, ceramic, cement, and glass industries. The glass industry may account for one-third to one-half of this sum. Inclusion of glass in the foregoing figures makes it difficult to calculate the total contribution of the mineral industry to the gross national product.

Average employment in 1962 in coal mines, quarries, iron and steel plants (excluding iron and steel foundries), and nonferrous plants totaled 180,000 workers of whom nearly half were employed in the coal mines. Employment in lime and cement plants and petroleum refineries may bring the total to 200,000 workers in a total industrial force of nearly 1 million. Employment in coal mines in 1963 totaled 84,605 persons, of whom 64,327 were underground workers.

PRODUCTION

The industrial production of Belgium is estimated to have increased almost 6 percent. However, mineral and metal output did not increase at the same rate. Pig iron production increased by 3 percent, steel ingots by 2 percent, and rolled product by 7 percent. The coal in-

[1] Foreign minerals specialist, Division of International Activities.

Digitized by Google

dustry halted the downward trend in production, and output was slightly higher than in 1962. Cement production continued at about the same rate, but there were advances in nonferrous metal production.

Production trends during 1959–63 showed significant increases over the 1959 output for iron and steel, copper, and tin. Zinc production was below the 1959 level during 1962 and 1963.

A high level of construction and public works stimulated production of quarry and pit products. All of these products except clays and quartzite showed large increases during 1959–63.

Expansion of petroleum refinery capacity led to substantial increases in the output of petroleum products, making the country a net exporter in 1963.

TRADE

Although all trade statistics refer to the Belgium-Luxembourg Economic Union (BLEU), Belgium's share of total trade, except in steel, is paramount. In 1963, 72 percent of the steel exports were from Belgium and 28 percent were from Luxembourg.

The total value of imports of minerals and metals in 1962, exclusive of diamond, was $1,135 million, or 25 percent of total BLEU imports. Fuels constitute the largest import group. The net cost of fuel imports during 1958–62 increased steadily from $227 million in 1958 to $298 million in 1962.

Exports of minerals and metals, valued at $1,395 million, accounted for 32 percent of all BLEU exports. In value, iron and steel ranked first in exports. In 1963 steel made up 20 percent of all BLEU exports.

Trade in diamond (industrial and gem) totaled $340 million, divided almost equally between imports and exports.

In 1962, 55 percent of all BLEU exports were to the European Economic Community (EEC). About 52 percent of mineral and metal exports were also to the Community. Of the total exports of treaty steel items (6.4 million tons) in 1962, 3.1 million tons was shipped to the Community. Steel semimanufactures covered by the European Coal and Steel Community treaty exclude forgings, cold drawn wire, pipes, and pipe accessories.

TABLE 2.—Belgium-Luxembourg: Value of metal and mineral trade in 1962

(Millions)

Commodity	Imports	Exports	Commodity	Imports	Exports

[1] Data not available.
[2] Outside DeBeer's Central Organization except for 1962, which includes 96,620 carats from within the organization.

Although France continued to be the main source for iron ore, Belgium decreased its dependence on Lorraine iron ore supplementing it with imports from Sweden. In 1963 Lorraine iron ore constituted 7.5 million tons out of a total of 14.4 million tons of imports. The iron content of Lorraine ore was 2.9 million tons compared with 2.12 million tons contained in 4.98 million tons of Swedish ore imported. France received large quantities of Belgium's iron and steel products, copper, and building and fluxing stone. In 1962, West Germany was Belgium's largest market for iron and steel and zinc and its second largest for copper. France was the largest market for copper and lead. Much of the trade of quarry and pit products was with The Netherlands which also was an important market for iron and steel, lead, copper, and zinc. The Republic of the Congo was an important supplier of nonferrous metals and minerals.

In 1962, Belgium's principal mineral and metal imports from the United States were lead, diamond, and sulfur. The United States was Belgium's largest single market for all types of diamond (except powder and splinters). The United States also received about 13 percent of the iron and steel products and 17 percent of the slab zinc exported from Belgium.

COMMODITY REVIEW

METALS

Ferrous Metals.—The Belgian iron and steel industry showed a slight gain in pig iron and crude steel output in 1963. The industry depended almost entirely on imported iron ore. Of the iron ore imports of

Digitized by Google

the Economic Union, nearly two-thirds was shipped to Belgian plants; the remainder was shipped to plants in Luxembourg. Flux limestone, dolomite, and nearly three-quarters of the coking coal requirements were met from domestic sources.

During 1954–63, production capacity for crude steel increased about 53 percent. Total investment in the iron and steel industry, including captive coke ovens, power generating and distributing facilities, and other general services amounted to $734.36 million during 1954–62. The steel production facility will be increased by the construction of a 1.5 million-ton plant at Selzacte and enlargement of plants of Société Anonyme Cockrill Ougrée from the existing 2.25-million-ton annual capacity to 3-million-ton capacity. The Chertal plant of Esperance-Longdoz with a steel capacity of 700,000 tons began production in May 1963, and was inaugurated officially in November.

TABLE 5.—Belgium: Rated annual production of the steel industry

(Thousand metric tons)

Commodity	1963	1965
Pig iron	8,010	9,070
Crude steel	[1] 8,855	10,320
Rolled steel	6,454	[2] 9,490

[1] Actual capacity at the end of 1963 may have been close to 10 million tons.
[2] In 1967.

Production.—In 1963 the average level of pig iron production was 86.8 percent of maximum capacity; the corresponding figure for crude steel was 85 percent.

Increased consumption of sintered ore in the blast furnace, noted since 1958 (when 926,000 tons of sinter ore was used), continued in 1963 reaching a total of 5,153,000 tons. A reverse trend in coke consumption per ton of pig iron was noted—757 kilograms in 1963, compared with 980 kilograms in 1956.

Thomas steel constituted 87.28 percent of total steel output in 1963 compared with 82.5 to 86.7 percent of total production during 1954–62. Open-hearth steel and electric furnace steel accounted for the remainder of the crude steel output. Production of electric steel in 1963 was abnormally low because of an accident in one of the plants. Belgium began producing Linz-Donawitz-Arbed-Cnrm(LD–AC) oxygen-converter steel in the Ougrée plant of Société Anonyme Cockerill-Ougrée. The same company was building similar facilities in the Les Forges de la Providence plant.

Belgium produced a relatively small quantity of alloy and special steel. Of the ferroalloys, only ferromanganese is produced.

In 1962 rolled steel was produced in 35 mills, 19 of which were part of an integrated complex; 16 were independent installations.

Output of flat products in 1963 was nearly twice that of 1956. Much of the investment in the Belgian iron and steel rolling mills has been in facilities for production of flat products.

Hainaut and Brabant Provinces supply about 60 percent of the pig iron and steel output; Liege and Luxembourg Provinces supply the remainder. Société Anonyme Cockerill-Ougrée, with plants at Seraing, Ougrée, Athus, Grivegnée, Tilleur, and Ferblatil, is the largest producer of crude steel (2.2 million tons in 1960). Other important producers are Société Anonymes des Láminoirs, Hauts-Fourneaux, Forges, Fonderies et Usines de la Providence, Société Métallurgique Hainaut-Sambre (1.2 million tons of crude steel in 1960), and Société Anonyme Métallurgique d' Espérance-Longdoz which produces mostly flat products. With the inauguration of the Chertal plant, Espérance-Longdoz attained 1.5 million tons annual production capacity.

Thomas slag was an important byproduct of the steel furnaces. Output in the first 9 months of 1963 was 986,000 tons. In 1961 and 1962 Belgium exported 1.2 million and 1.6 million tons of Thomas slag, respectively.

TABLE 7.—Belgium: Composition of rolled-steel production

(Percent)

Type of product	1952	1956	1961	1962
Flat products	38.1	40.1	42.7	42.9
Bars and rods	40.3	39.6	39.5	38.4
Wire	10.5	10.5	12.6	11.8
Sections, rails, accessories	10.4	8.8	5.1	6.8

Consumption and Trade.—In 1962 the Belgium-Luxembourg Economic Union exported 514,000 tons of ingots and other primary forms of steel. A total of 6.995 million tons of rolled steel, pipes and accessories and other products also was exported. The total value of these exports was $836 million.

Total sales of Belgian steel increased slightly. For the first time exports to European Coal and Steel Community (ECSC) countries (2.40 million tons) exceeded exports to other countries (2.07 million tons). Steel products supplied to the Belgian market totaled 2.7 million tons including 1.74 million tons of Belgian steel and 510,000 tons of steel from Luxembourg. Imports were 486,000 tons of which 400,000 tons were from ECSC countries. In order of importance, principal consumers were plants making wire products and tubes, metal construction, and sheet-working industries. About 40 percent of steel delivered to domestic consumers was reexported after fabrication or transformation.

New Plants.—Sidmar, a new steel concern was established in Belgium in 1962 with participation of Belgium, Luxembourg, and French capital. The company's investment program calls for the building of a steel complex with two large-capacity blast furnaces, a Linz-Donawitz steel works with three converters, a slabbing mill, an 80-inch continuous hot wide-strip mill, and an 80-inch four-stand tandem cold mill. Crude steel production is not expected before 1967, but the cold mill may start operation in 1966.

[1] Includes France 989; Germany 666; Netherlands 484; Italy 257; Luxembourg 7.
[2] Includes United States 580; United Kingdom 128; other European countries including Eastern Europe 525; Puerto Rico 95; Canada 83; Latin American countries 181; Middle East including United Arab Republic (Egypt) and Turkey 236; African countries except United Arab Republic (Egypt) 140; other 102.

The Chertal plant of Espérance-Longdoz, which started operating in 1963 (first steel poured in May and first hot-rolled coil produced in August), comprises two converters, each 145-ton capacity, which produce LD and LD–AC steel. Pig iron for the converters is shipped from the company's plant at Seraing, 17 kilometers away. The rolling slabbing mill and wide-strip mill produce hot coils which are shipped to the Jemeppe plant of Espérance-Longdoz for cold reduction.

Nonferrous Metals.—Belgium depended entirely on foreign metals, ores, concentrates, and scrap for its large nonferrous smelting, refining, and rolling mill industries.

Of the items imported, which were valued at $376 million in 1962, copper comprised two-thirds of the metal imports and zinc concentrates comprised more than half of the ores and concentrates. In 1962 the Republic of the Congo was the source for 60 percent of copper ingots, 49 percent of crude tin, 31 percent of slab zinc, 12 percent of the zinc ore, and 82 percent of the tin ore. Virtually all the primary germanium, selenium, cobalt, uranium, and radium and important quantities of secondary cadmium, precious metals, and other nonferrous metals were obtained from raw materials produced in the Congo. West Germany and the United States were important suppliers of pig lead, France of aluminum, and the United Kingdom of copper.

TABLE 10.—Belgium: Imports and exports of nonferrous metals, ores, and concentrates in 1962

	Quantity (metric tons)	Value (millions)		Quantity (metric tons)	Value (millions)
Imports:			Exports:		
Metals	443,370	$261	Metals	400,525	$215
Semimanufactures	24,539	25	Semimanufactures	139,971	91
Ores and concentrates	838,553	58	Ores and concentrates	79,188	4
Scrap and metallic waste	214,168	32	Scrap and metallic waste	74,929	11
Total value		376	Total value		321

Source: Computed from data presented in L'Économie Belge en 1962, Ministère des Affaires Économiques et de l'Énergie, Direction Génerale des Études et de la Documentation.

The products of the smelting and refining operations are exported as ingots and as rolled and extruded semifinished products. France, West Germany, and The Netherlands were the main recipients in the Common Market. The United States also imported significant quantities of zinc, cobalt, and cadmium from Belgium.

Copper, lead, and zinc account for about 95 percent by weight of all nonferrous metal output.

The remaining 5 percent comprised antimony, arsenic, cadmium, cobalt, columbium, gallium, indium, gold, silver and platinum metals, selenium, tantalum, and uranium. The cobalt was recovered from imported copper-cobalt alloys; germanium and uranium were recovered from imported concentrates. The other metals are byproducts of refining imported copper ingots and treating imported copper, lead, and zinc ores and scrap.

Production figures for the individual metals, other than tin, are not available, but current annual production rates may be estimated in tons as follows: antimony 1,500 to 2,000; cadmium 600 to 700; cobalt 2,000 to 3,000; germanium 80; sellenium 15 to 20; uranium oxide 250 to 400; and silicon 10 to 20. Precious metal production is 12 to 14 million ounces, of which 80 to 90 percent is silver. Much of the output is exported.

Belgium's consumption of principal nonferrous metals in 1962 follows:[2] aluminum 67,500; copper 65,300; lead 52,400; tin 3,200; zinc 122,100 tons.

Nonferrous metal smelting and refining in Belgium were dominated by two companies, the Société Générale Métallurgique de Hoboken and the Société des Mines et Fonderies de la Vieille-Montagne, with headquarters in Brussels and Angleur, respectively. Hoboken produces nearly all the copper, tin, and cobalt, and 50 percent of the lead. Vieille-Montagne controls 50 percent of the zinc and about 33 percent of the lead capacity. Both companies are also responsible for a large share of the output of minor metals.

Aluminum.—Because Belgium does not produce primary aluminum imported bauxite and hydrous and calcined alumina were used in the chemical industry and for making abrasives. The output of rolled and extruded aluminum products has increased from 26,700 tons in

[2] Metal Statistics 1953–1962. Metallgesellschaft Aktiengesellschaft, 50th annual issue, Frankfurt am Main 1963.

Digitized by Google

1955 to 80,700 in 1962. Annual capacity in 1963 was probably 100,000 tons.

Of the six companies that have aluminum rolling mills plants of Société Industrielle de l'Aluminum at Duffel, Laminoirs de L'Escaut at Burcht, and Aleurope in Ghlin-Baudour are the largest. Laminoirs de L'Escaut was planning to increase its capacity from 15,000 to 50,000 tons per annum.

Duties on aluminum ingot import from countries other than those of the Common Market and associated overseas countries were increased from 2 to 3 percent on January 1, 1963.

TABLE 11.—Belgium: Principal nonferrous metallurgical plants

Company and plant	Type of plant	Annual capacity (tons)	Remarks
Société Générale Métallurgique de Hoboken:			
Hoboken	Copper smelter	24,000	Antimony, bismuth, cadmium, cobalt, mercury, platinum, selenium, tantalum, various metal powders, and salts are recovered.
	Lead smelter and refinery	75,000	
	Tin smelter and refinery	10,000	
	Refinery for gold	75	
	Refinery for silver	500	
	Antimony refinery		
Olen	Electrolytic copper refinery	205,000	Refined copper and mill products, cobalt (powder, oxide, and salts), radium, silicon, and nuclear-grade uranium are produced.
	Copper mill		
	Cobalt refinery		
	Germanium refinery	60	
	Uranium refinery	650	
Société des Mines et Fonderies de Zinc de la Vieille-Montagne:			
Flône	Zinc smelter	48,000	
Valentin-Cocq	Zinc smelter	30,000	
	Zinc white	16,000	
Angleur	Zinc smelter and rolling mill	30,000	
Tilff	Zinc rolling mill	15,000	
Balen	Zinc refinery and rolling mill	65,000	In the Balen plant arsenic, bismuth, cadmium, copper, germanium, gold, silicon, and silver are recovered as byproducts.
	Lead smelter	42,000	
Campagnie des Métaux d'Overpelt-Lommel et de Corphalie, A.S.:			
Overpelt	Zinc refinery	40,000	Horizontal retort furnaces; refining by distillation; cadmium and silver as byproducts.
Lommel	Zinc rolling mill		
	Lead smelter	18,000	
	Zinc refinery	48,000	
	Lead rolling mill		
Société Industrielle d'Aluminum: Duffel.	Aluminum rolling mill	60,000	Largest plant in the country.
Laminoir de l'Escaut: Burcht	do.	15,000	Producer of sheets.
Aleurope: Ghlin-Badour	do.	12,000	Producer of sheets; owned 50 percent by Reynolds International, Inc.

Copper.—Belgium's copper industry is largely confined to electrolytic refining of imported blister and scrap, although annually 10,000 to 12,000 tons of copper metal also are produced from ores and concentrates.

Electrolytic copper was both exported as such and used domestically for production of semimanufactures of copper and copper alloys which also are exported in substantial quantities. Copper also is exported as sulfate; 1962 exports totaled about 12,800 tons.

Digitized by Google

Lead.—Seven companies with a total annual smelter capacity of 150,000 tons produced pig lead, Hoboken, Vieille-Montagne, and Overpelt-Lommel account for 50, 28, and 12 percent of production, respectively.

A large part of lead concentrates for the Belgian industry has been imported from the Tsumeb Corporation mine in South-West Africa. However, in 1962, this company installed a lead smelter and it was reported that export of concentrate to Belgium was to stop at the end of 1963. To replace concentrate from this source, the Société Générale des Minerais in 1962 made a 12-year contract with the Brunswick Mining and Smelting Corp. of Canada for supply of lead and zinc concentrates from the Bathurst mine. The Société Générale des Minerais supplied $11 million for financing development of the property and is to buy all concentrates produced during the first 5 years and all concentrates not required by Brunswick during the succeeding 7 years. This mine is expected to come into production in early 1964.

Zinc.—In 1963 Belgium was the world's fourth largest zinc producer. The country ranked first in Europe. Capacity is estimated at 350,000 tons, of which 65,000 tons is electrolytic (Balen refinery of the Vieille-Montagne).

About half of the zinc output was exported. The remainder was used domestically for galvanizing and for making mill products, zinc sulfide, and lithopone, largely for export.

Other Nonferrous Metals.—All primary tin is produced in the Hoboken plant which has the capacity to smelt 18,000 tons of concentrate. Nearly half of the tin supply is used by the steel industry in making tinplate.

Imported lead ores are the source for antimony. The principal producer is at Campine. Belgium was a leading cobalt and cadmium producer. The cadmium was recovered largely from imported zinc ores. The cobalt refinery at Olen was the second largest in the world and treated imported cobalt-copper alloys and cobalt concentrates.

According to the 1962–63 annual report of the Société Générale Métallurgique de Hoboken, because of large stocks of germanium at the Olen plant, production during this period was confined to monocrystals and to polycrystalline metals in special forms. The radium facility at Hoboken was at a standstill; sales were from stocks. The plant installed facilities for making enriched U_{235}. Imported uranium concentrates also are treated in this plant which produces uranium oxide, salt, and refined metal. Métallurgie et Mécanique Nucléaires of Dessel, established in 1962, made nuclear fuel elements.

The Société Anonyme Fansteel-Hoboken, established in November 1962 with a capital of US$7,200,000 commenced its activities on January 1, 1963. Fansteel Metallurgical Corporation of Chicago and Société Générale Métallurgique de Hoboken each have 50 percent of the shares of the new firm. The company will produce high-temperature metals—columbium, tantalum, tungsten, and molybdenum—and powder from these metals.

NONMETALS

The principal nonmetallic raw materials produced in Belgium are building stone such as marble, porphyry, limestone, slate, sand and

Digitized by Google

gravel from pits and from dredging of rivers, clays, dolomite, chalk, and marl. These are used mainly in the building industry with subordinate uses as fluxing limestone, refractory material, and glass sand. Domestic output meets the demand for cement, lime, common brick, pipe, wall and floor tile, structural glass, and most types of building stone. These quarry and pit products enter Belgium's foreign trade in significant quantities. In 1962 the total imports and exports were, respectively, 7.2 and 8.2 million tons. Thomas slag, cement, rejects of the steel industry, and various other mineral matter added 4.8 million tons to the exports and 610,000 tons to the imports.

Industrial minerals are imported. Of these, the most important are diamond for the cutting and polishing industry, fertilizer raw materials, sulfur, salt for both human consumption and the chemical industry, and gypsum. Imports and exports of all nonmetallic minerals into Belgium in 1962 were valued at $62.7 million and $46.5 million, respectively. These values do not include fired clay products such as brick, tiles, or ceramic and glass products; and diamond. In terms of value, Thomas slag and cement were the most important exports ($23.1 million and $16.7 million, respectively). Among the imports, phosphate rock ($11.1 million), asbestos ($8.4 million), clays ($4.7 million), salt ($4.6 million), and sulfur ($4.5 million) were the most important.

Cement.—In 1963 Belgium produced 1.2 percent of the world cement output. As a result of consolidation of producers in the last decade, 1963 output was obtained from relatively few plants. In 1959, the industry's capacity was estimated at 7.4 million tons in 18 plants—12 portland cement plants, 5 blast furnace slag cement plants, and 1 plant making both types.

Most of the cement plants are concentrated in the chalk, limestone and clay regions of Tournai, Mons, and Harcourt-Visé. Plants using blast furnace slag operate in the vicinity of the iron and steel centers of Charleroi and Liége. The industry's three leading producers were Ciments d'Oburg, Cimenteries et Briqueteries Réuniés (a subsidiary of Société Générale de Belgique), and Compagnie des Ciments Belge. The latter company primarily makes blast furnace slag cement; the other two make portland cement.

In 1962 nearly 27 percent of the domestic production was exported. The Netherlands, the only neighboring country with insufficient cement production, was the largest importer. Natural waterways and inland canals are used for transporting cement.

Clays.—Commercial deposits of common clay are abundant. The relatively large quantities of clay produced and imported are used in the manufacture of bricks and tiles and in a variety of fired products such as earthenware, stoneware, vitrified porcelain, and refractory products. The imported clay was principally refractory grade. West Germany was the principal source.

Diamond.—Industrial and gem quality diamond, bort, and powder are imported into Belgium, worked, and then re-exported as faceted and polished stones, graded and sorted industrial diamond, and bort powder and splinters. Because of the emergence of important diamond-polishing industries in Israel, West Germany, the United States, and other countries, Antwerp has lost its preeminent position as a

Digitized by Google

diamond-polishing center, although it is still the world's leading diamond-cutting center. In 1963, 10.1 million carats of diamond valued a $189 million was shipped to world markets; imports were 13.1 million carats valued at $193 million. Values of imports and exports of diamond in 1962 were about $170 million each. The increase of trade over that of 1962 resulted principally from higher imports of stones suitable for cutting and exports of polished diamonds. Trade in industrial diamond declined.

The United States was the most important single market for both gem and industrial diamond exported from Belgium. In 1963, exports to the United States accounted for 29 percent of the industrial, 41 percent of the polished stone, and 33 percent of the bort. The United Kingdom was also an important recipient of bort; its 1963 share was roughly the same as for the United States.

At the end of 1962, 12,136 workers and 2,200 apprentices were registered under the social security system as engaged in the diamond industry.

TABLE 12.—Belgium: Diamond trade in 1963

	Quantity (thousand carats)	Value (thousand U.S. dollars)	Average value per carat (U.S. dollars)	Principal sources and destinations (thousand carats)
Imports:				
Gem quality:				
Crude	4,421	107,226	24.25	United Kingdom 3,714 (including 294 outside Diamond Trading Corporation); United States 300; Liberia 104; France 88; Congo (Brazzaville) 80; Israel 37.
Polished	299	50,080	167.67	Israel 139; South Africa 56; United Kingdom 33; India 27; United States 18.
Industrial	5,148	27,562	5.35	United Kingdom 1,805 (including 1,689 outside Diamond Trading Corporation); Congo (Brazzaville) 1,715; United States 581; Ghana 490; Liberia 205.
Bort and powder	3,258	8,406	2.58	United Kingdom 1,298; Congo (Brazzaville) 1,066; United States 529; Switzerland 236.
Exports:				
Gem quality:				
Crude	354	17,592	49.72	United States 125; Netherlands 60; India 56; Israel 40; United Kingdom 31.
Polished	1,177	132,337	112.43	United States 481; Hong Kong 147; United Kingdom 128; West Germany 69; France 51; Singapore 47; Switzerland 37.
Industrial	3,963	27,552	6.95	United States 1,167; United Kingdom 823; Netherlands 560; Israel 236; U.S.S.R. 190; Czechoslovakia 181.
Bort	3,372	8,798	2.61	United States 1,117; United Kingdom 1,062; West Germany 253; Netherlands 192; Switzerland 188; Czechoslovakia 147; France 134; Japan 102.
Powder and cleaned splinters.	1,194	3,023	2.53	West Germany 311; Switzerland 223; Netherlands 141; Israel 138; Japan 84; United States 80; France 71.

Fertilizer Raw Materials.—Belgium is a leading European producer and supplier of phosphate, potash, and nitrate fertilizers produced from imported crude raw materials and atmospheric nitrogen. Sulfuric acid for superphosphate production is made from imported elemental sulfur and as a byproduct in the processing of metallic sulfide minerals. Morocco is the principal source of the phosphate, France and West Germany for the potash, Chile for the nitrate, and the United

758-002—65——26

Digitized by Google

States and France for sulfur. Most of the nitrogen fertilizer was produced by nitrogen fixation. In 1962, 22,000 tons of crude sodium nitrate was imported and 281,000 tons of nitrogen in nitrogen fertilizers was produced.

Sand and Gravel.—Sand was produced domestically for the metallurgical industry, for glassworks, and as concrete aggregate. Of the total sand production of 6.8 million tons in 1962, 1.4 million tons was glass sand, 1.0 million tons was for the metallurgical industry, 3.2 million tons was for building sand, and 1.1 million tons was for miscellaneous uses. Availability of large deposits of high-quality sand in Belgium has helped make Belgium the world's largest exporter of flat glass products. These exports amounted to nearly $104 million in 1962.

Belgium has a substantial net import of metallurgical and building sand. Sand and gravel was obtained from large dragline operations in the principal rivers and from exploitation of extensive pits.

Other Nonmetals.—High-quality limestone and marble (including a famous black marble occuring along the Meuse River) are produced for construction. Other stones produced are dolomite, porphyry, sandstone, chalk, marl, and calcareous tuffa. Slate is mined underground in the southern part of the country and is used mainly as roofing material, floor slabs, etc.; however, the output has been declining.

Belgium exports substantial quantities of dolomite in both crude and calcined forms. The 1962 exports may have equalled half of the tonnage of crude dolomite produced in the country.

The pumice imported from West Germany is used not as an abrasive but as a lightweight aggregate.

MINERAL FUELS

Energy requirements of Belgium are met by coal, wood, methane drained from coal mines, hydroelectric plants, and petroleum. Total gross internal apparent consumption of energy in 1962 is provisionally given as 39.2 million tons of standard coal equivalent. Coal and petroleum supplied 68 and 31 percent of the total, respectively. Relative positions of coal and petroleum have changed considerably in favor of petroleum. In 1952, the shares of coal and petroleum in total gross apparent energy consumption were 85 and 12 percent respectively. The balance of trade for solid fuels (coal, lignite, and briquets) has also changed; Belgium is a net importer.

Coal.—Reduction in coal production during 1959–63 resulted from a program which closed high-cost mines. In accordance with an agreement with the High Authority of ECSC, the Belgian Government undertook to reduce coal production capacity by 9.5 million tons over the 5-year period 1959–63. To meet this schedule, mines with a total capacity of 2.7 million tons had to be closed by the end of 1963. In midyear the government asked the High Authority of the ECSC for authorization to suspend mine closures of the remaining 1.8 million tons of capacity scheduled to be taken out of production by yearend. In justifying the request, the Belgian Government cited shortages of household coal developed in the severe winter of 1963 and pointed out the fact that since January 1, 1963, the coal industry has not benefited

Digitized by Google

from the protection offered under ECSC Treaty, Article 37, which restricted Belgian coal trade. The government also felt it unwise to close coal mines at the time when imports were increasing. The High Authority seemed willing to agree to the cessation of mine closures; only one mine was closed during the year. Thus the production rate may be stabilized at about the 1963 level.

Production of each of the coalfields of Belgium in 1963 and their relative shares in total output follow: Campine 10,067,000 tons (47 percent); Liége, 3,082,000 (14.4 percent); Charleroi 5,317,000 (24.8 percent); Centre 1,081,000 (5.1 percent); and Mons 1,871,000 (8.7 percent). Because mine closures have been in the southern fields, the share of the southern basins (Mons, Centre, Charleroi, and Liége) in total production diminished from 68 percent in 1952 to 53 percent in 1963. In 1963 the output per underground worker per day for the southern basins was 1.630 tons compared with 2.09 tons for Campine. The corresponding figures for 1960 were 1.452 and 1.792 tons per day, respectively.

Of the apparent consumption of 27.6 million tons in 1963, 20.3 million tons was supplied by Belgian coal and 7.3 million tons by imported coal. The domestic industry supplied nearly 68 percent of the 9.6 million tons of coking coal delivered to coke plants. A greater need for imported coal is predicted to cover anticipated rise in coal needs reflected in forecasts of the supply position for 1956–66.

Mine closures have improved the market for coal and reduced stocks of coal at Belgian mines. Since 1957 Belgium has been a net importer of coal.

TABLE 13.—Deliveries of domestic and imported coal to consumers

(Thousand metric tons)

End use	1962	1963	End use	1962	1963
Coke and gas ovens	9,567	9,660	Mine use (powerplants, issue to miners, etc.)	2,497	2,580
Thermal power stations	4,262	4,113

In 1960, the ECSC High Authority isolated the Belgian coal market by setting a quota system for coal imports into Belgium, thus limiting competition from Common Market and other suppliers. This was one of the special measures taken by the High Authority to improve the competitive position of the Belgian coal industry during a transitional period. In January 1963 the quota was removed for the Common Market. This quota apparently applies to coking coal for making coke, for domestic industry, and for reexport. Other coals are free of restrictions and their imports are limited by commercial considerations.

Imports of U.S. coal in 1963 totaled 2 million tons, of which approximately 1.5 million tons was coking coal for Belgian use and for processing and reexport, 400,000 tons anthracite, 60,000 tons anthracite fine, 100,000 tons low-volatile steam coal fines and 30,000 tons semibituminous for railroad use. Of the coking coal, 100,000 tons was imported by a special authorization designed to increase coking coal stocks.

The requirements of the Belgian iron and steel industry and independent cokeries for coking coal in 1964 were estimated at about 9.4 million tons, of which about 6.4 million tons must be of domestic origin, leaving an estimated import requirement of about 3 million tons. The U.S. quota may equal half of the coking coal imports.

TABLE 15.—Belgium: Stocks of coal at mines and net imports

(Thousand metric tons)

[1] December.
[2] Dec. 31, cited.

The Belgian coal industry has several private organizations. Fédération Charbonnière de Belgique (Fedechar), the Federation of Belgian Coal Companies, is a coal producers' association embracing practically all producers. Fedechar represents the common interests of its members. The Comptoir Belge des Charbons (Cobechar) is a central sales organization for coal and briquet producers. Cobechar was authorized by the ECSC to sell fuels of all its member companies as a group. As of February 1963, Cobechar was also to deal through wholesale dealers. Smaller private organizations are concerned with health and safety, medical, social, and other aspects of the industry.

L'Institute National de l'Industrie Charbonnière (Inichar), National Institute of the Coal Industry, is a Government agency which carries out principally projects in technical matters and safety. In November 1961, the government established the Directoire de l'Industrie Charbonnière, with powers of decision and control over coal mines. However, the duties of this organization were a matter of negotiations with the High Authority. The High Authority felt that

Digitized by Google

the terms of reference of the act were incompatible with the Common Market Treaty, because it empowered a national body to take action which properly belongs to community institutions.

Petroleum.—Belgium does not produce petroleum or natural gas, but has an important refining industry. Of the country's six refineries, five are in Antwerp and one is in Ghent. Belgium's 1963 throughput capacity was 13.2 million metric tons, compared with 402,550 tons in 1950.

Some exploration for petroleum was carried out. The Belgian Shell Co. applied to the Ministry of Economic Affairs and Energy in March 1962 for exclusive petroleum exploration rights in west Flanders. The company was recently accorded exploration rights, although a formal agreement with the ministry has not yet been concluded. This company spudded a drilling rig in 1963 at Houtem near Veurne to study the geological structure of the area. Petrofina, having completed one hole in the Campine area in 1962, was expecting to drill again in this area. Petrofina carried out this operation for a partnership of Société Campinoise de Recherches et Exploration Minérales (SCREM) and other companies which in 1960 were granted exploration and exploitation permits for the Campine area in the Province of Limburg. The Bataafse Petroleum Maatschappij has exploration and exploitation rights for the area Entre Sambre et Meuse in Hainaut Province; however, the company has done only petrological investigations so far.

TABLE 16.—Belgium: Petroleum refineries

Company	Refinery location	Annual throughput capacity		Remarks
		Thousand tons per year	Barrels per day	
Société Industrielle Belge des Pétrole (S.I.B.P.).	Antwerp	8,500	190,000	Second largest refinery in Europe, owned equally by British Petroleum and Petrofina. Produces gasolines, diesel and fuel oils, and LPG.
Albatros S. A. Belge Pourle Raffinage de Pétrole.	do	(1)	14,000	The company is controlled by French and Belgian capital; produces gasoline, butane, and propane.
Raffinerie Belge des Pétroles (RPB).	do	1,260	30,000	Owned by Signal Oil Company.
Esso Standard Belgium	do	2,075	47,000	The firm has scheduled an expansion of its refining capacity by one-third, to be completed in 1964.
Anglo-Belge des Pétroles	do	150	3,500	
Belgian Shell Company	Ghent	130	3,000	The company produces principally bitumen and lubricants.

[1] Data not available.

Refinery throughput in the first 9 months of 1963 was 9.0 million tons (an annual rate of 12 million tons), compared with 8.5 million tons (64.6 million barrels) in 1962. Total refinery product output in 1963, based on the first 9 months (8.2 million tons), was 39 percent more than in 1962. In the first 9 months of 1963 the following four products accounted for 83 percent of total output: residual fuel oil 36 percent, diesel oil 22 percent, motor gasoline 13 percent, and light residual oil 12 percent.

Digitized by Google

In spite of an increase in refinery capacity in recent years, until the end of 1962 Belgium was a net importer of petroleum products. In this year imports exceeded exports and bunkering by about 834,000 tons. However, in the first half of 1963 Belgium became a net exporter of about 371,000 tons of products. Petroleum bunker loadings by foreign aircraft and vessels engaged in international trade rose by 35 percent in 1962 over those of 1961.

Delivery of products to inland consumers increased at an annual rate of about 11 percent. However, the rate of increase for gas and diesel oil was 17 percent annually. Industry and transportation rank almost the same as consumers, each accounting for about 30 percent. Space heating and lighting follow next in consumption with about one-fifth of the total.

TABLE 17.—Belgium: Delivery of petroleum products to internal consumers

(Thousand metric tons [1])

Product	1959	1960	1961	1962
Motor and aviation gasoline [2]	1,296	1,235	1,306	1,370

The Mineral Industry of Bulgaria

By K. P. Wang [1] and Roman V. Sondermayer [2]

BULGARIA has a diversified mineral industry and produces not only for domestic consumption but also for export, mainly to other East European countries. The more prominent minerals, with output in percentages of the 1963 world totals, follow: Lead, 2; mine zinc, 1.6; and barite, cement, chromite, coal, copper, diatomite, fluorspar, gypsum, iron ore, manganese ore, pig iron, pyrite, salt, steel ingots, and sulfur 0.1 to 1.0 each.

Mineral output value, up to the refined product stage, represented approximately 6 percent of the gross national product in 1963. The mining industry alone employed about 120,000 workers, or a fifth of the country's industrial labor. Mineral exports, predominantly nonferrous metals, continued to be an important source of foreign exchange. Bulgaria's mineral expansion program, carried out with considerable U.S.S.R. technical and financial assistance, was moving so fast that many economic and technical problems were created.

The most important mineral developments in 1963 concerned iron and steel and petroleum. The Kremikovtsi iron and steel plant began partial operations late in the year and, when completed, will be Bulgaria's largest integrated steelworks. The Burgas petroleum refinery, built to process Soviet crude, also was commissioned in 1963. Annual capacity of the refinery will be 1 million tons of crude upon completion of the first stage, and 2 million tons upon completion of the second stage.

Developments in the nonferrous field were limited to modernization and expansion of existing facilities. Construction continued on the lead section of the well-known Plovdiv lead-zinc smelter and the beneficiation plant of the Medet copper project; the latter is scheduled to become one of the largest of its kind in Bulgaria.

Shortages in electric power and skilled workers contributed to lagging productivity in Bulgaria's mineral industry in 1963. Construction of various new powerplants was initiated to compensate for the deficiency in electricity. Night schools were established to train additional workers in the installation, operation, and maintenance of equipment. Many of these workers were recruited from farms.

PRODUCTION

Production of minerals and metals has shown steady increases in recent years. Bulgaria's 1963 output plans were fulfilled and certain

[1] Chief specialist, East Europe–Far East, Division of International Activities.
[2] Foreign mineral specialist, Division of International Activities.

Digitized by Google

long-term targets were revised upwards. The rate of mineral output increase in 1963 was 10 percent higher than in 1962. The largest advance took place in nonferrous metals. Output of electrolytic copper and steel doubled during 1959–63, and refined zinc production went up more than five times. Lignite output has steadily increased, whereas brown coal output has reached a somewhat stabilized level.

TABLE 1.—Production of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:

Coke—do	9	20	20	8	(2)
Petroleum, crude—do	192	200	207	199	(2)

[1] Bulgaria also produced 1,000 tons of asbestos, 62,000 tons of china clay, and substantial barite in 1963.
[2] Data not available.
[3] Barite has been produced in significant quantities, but no output data are available. Imports by the U.S.S.R. alone were 12,900 tons in 1961 and 21,500 tons in 1962.
[4] Estimate.

TRADE

Minerals and related products have been important in both the export and import trade of Bulgaria in recent years. The latest figures available, for 1962, showed that mineral exports totaled 96.7 million leva (1.27 leva equals US$1), or 13.2 percent of all exports. Ores and concentrates of nonferrous metals accounted for about half of the mineral exports by value and aggregated over 100,000 tons.

Imports of minerals and related products plus capital goods used by the mineral industry accounted for 259.6 million leva, or a third of the country's total imports in 1962. Ferrous products headed the list of mineral imports, with 43 percent of the total. Fuels ranked

Digitized by Google

next, accounting for about one-fifth of mineral imports. The Bulgarian Government expects to reduce the annual imports of steel products when the Kremikovtsi plant is in operation. However, no programs were in sight to substantially reduce coal and coke imports below the million-ton annual level and petroleum product imports below the 1.5-million-ton level.

Bulgaria's principal trading partner has been the Soviet Union; about four-fifths of all trade has been with that country in recent years. In 1961, the U.S.S.R. supplied Bulgaria with half of its imports of mineral industry machinery and equipment, three-fifths of the mineral raw materials including fuels, and half of the ferrous metals. With the completion of the Burgas refinery, Bulgaria probably will import an additional 1 to 2 million tons of crude oil annually from the Soviet Union but may reduce refinery product imports.

TABLE 2.—Exports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal countries of destination, 1962
Metals: [1]			
Iron and steel:			
Iron ore	12,181	27,952	Hungary 18,381; Rumania 9,571.
Steel	1,057	----------	[2] Italy 804; Hungary 253.
Lead [3]	20,258	18,013	Poland 4,773; Netherlands 2,023; U.S.S.R. 1,504.
Zinc [3]	13,757	40,358	West Germany 10,196; Czechoslovakia 8,744; Netherlands 6,679.
Nonmetals:

Bitumen	15,200	15,800

COMMODITY REVIEW

METALS

Iron and Steel.—The new Kremikovtsi iron and steel plant, covering 6,000 acres, is based upon an extensive local deposit of complex ore containing 30 to 46 percent iron and variable amounts of barite, silver, and manganese. The first of its two blast furnaces started operating in November 1963. When completed, the enterprise will also have a large open-pit mine, an iron ore beneficiation plant, barite recovery facilities, a coking plant, three oxygen converters, a steel-rolling mill, a cement plant, limekilns, and auxiliary workshops and laboratories.

The mine will yield 1.2 million tons of beneficiated iron ore annually during the initial stage and about 5 million tons ultimately. The two blast furnaces and two batteries of byproduct ovens are expected to produce annually a total of 1,120,000 tons of pig iron and 600,000 tons of coke. The three converters will have a combined annual capacity of 1,150,000 tons of steel, and an electric furnace will have a capacity of 150,000 tons. The rolling mill is designed to produce about 1 million tons of steel products per year.

Because Kremikovtsi only started production late in the year, the Lenin steelworks remained the foremost iron and steel producer during 1963. At the Lenin plant, construction of the sixth 70-ton Siemens Martin furnace was underway.

Nonferrous Metals.—During 1963, nonferrous metals were the most important branch of Bulgaria's mineral industry in output value. Quantities of lead, zinc, and copper produced in excess of requirements were available for export. Plant modernization and reconstruction

Digitized by Google

were major goals of management. Automation was introduced in many instances, and technologic processes were improved.

At the Plovdiv lead-zinc smelter, annual zinc capacity was expanded by 2,500 tons over the existing 30,000 tons through the installation of additional roasting facilities and six rectifiers for electrolysis. Cadmium capacity already installed was about 80 tons per year. The Bulgarians were planning to complete the lead division, ultimately to be rated at 40,000 to 50,000 tons of refined lead, before the end of 1963. Sulfuric acid facilities capable of producing 20,000 tons annually, about a third of the proposed capacity, were installed during the year. Plovdiv is slated to become a modern, fairly large nonferrous smelter.

Medet became the largest mine copper producer of Bulgaria, far ahead of Burgas in terms of daily output. Apparently, Medet was producing at an annual rate of about 4 million tons of 0.43 percent copper ore at the end of 1963, half the target for 1965. When completed, the mine may be capable of supplying 25,000 tons or more of contained copper yearly. Development of a new copper mine near Radka was behind schedule. The bulk of Bulgaria's copper concentrate was smelted at the Damyanov copper smelter in Pirdop, which had an annual capacity of about 20,000 tons at the end of 1963 and was due for substantial expansion.

NONMETALS

Abrasives.—The first abrasives plant in the country was under construction at Berkovitsa with Soviet technical assistance. Due for completion by 1964, the plant will have a yearly capacity of 2,500 tons of abrasive materials.

Cement.—During 1963, cement maintained its leading position among Bulgaria's nonmetallic mineral industries. Output increased slightly in all of the five existing plants, which are located in Dimitrovgrad, Devniya Reka, Temelkovo, Vratsa, and Pleven. At Devniya Reka, a new cement plant or an extension of the first one was scheduled for construction. The Kremikovtsi cement plant, planned for 1965, will be rated at 1.2 million tons annually. Bulgaria's 1963 total cement capacity was just above 2 million tons.

Fertilizers.—Reconstruction and expansion of the fertilizer plant at Stara Zagora was completed during 1963. Its annual capacity, about twice that of the Dimitrovgrad plant, is approximately 500,000 tons of nitrogenous fertilizers.

MINERAL FUELS

Coal.—Bulgarian coals, predominantly brown coal and lignite, were the most important energy sources in 1963. Brown coal output was static, whereas lignite output increased considerably over that of 1962. Production of bituminous coal remained small, although a new cleaning plant was placed in operation at Sliven to supply coking coal to the Kremikovtsi iron and steel plant. Only negligible quantities of anthracite were extracted in 1963. As in previous years, Bulgaria relied heavily on imports to meet its coke and anthracite requirements.

Most of the country's coal activities were centered around the

Digitized by Google

Maritza lignite basin, where open-pit operations were scheduled to furnish 15 million tons of lignite annually. Development of electrical generating capacity at the mine site was the basic approach to greater utilization of Maritza lignite. In the Sofia area, Bulgaria's second ranking but much smaller lignite basin, a new 350,000-ton-per-year mine started production in 1963. The mine is scheduled to be expanded to 1 million tons by 1965. Expansion of lignite operations is the most important part of Bulgaria's program to raise overall coal output to 37 million tons by 1965.

Petroleum and Natural Gas.—Bulgaria's small oil and gas industry, which provided only a minor share of overall requirements, was given encouragement for future expansion in 1963, as a result of discoveries of oil and gas fields near Dolni Dubnik in the Plovdiv area of northern Bulgaria. After the original discovery, all petroleum-drilling equipment and activities were concentrated in this area. Not much natural gas was utilized in Bulgaria in 1963, but plans were made to develop industrial markets near the gasfields.

A new refinery with 1 million tons of throughput capacity for processing Soviet crude was commissioned in Burgas on the Black Sea during 1963. When the second phase is completed, refinery output is expected to include about 610,000 tons of diesel fuel, 270,000 tons of gasoline, 600,000 tons of heating oil, and 60,000 tons of metallurgical fuel. A plant for producing ethylene, a basic raw material for making polyethylene and synthetic rubber, will be erected near the oil refinery.

The Mineral Industry of Czechoslovakia

By Roman V. Sondermayer [1] and K. P. Wang [2]

CZECHOSLOVAKIA is one of the most industrialized of the Communist nations and has extensive metallurgical and fabrication facilities. However, except for coal and magnesite, its mineral resources are relatively limited, and substantial imports of mineral raw materials, primarily from the U.S.S.R., are necessary in order to make the many industrial products needed by the economy.

The more prominent mineral and metal products produced in 1963, in percentages of world totals, were roughly as follows: Magnesite 7; coke 6; coal 3 to 4; pig iron and steel 2 to 3; antimony 3; graphite 2; and aluminum, barite, cement, feldspar, gypsum, iron ore, kaolin, limestone, lead, manganese, pyrite, tin, and zinc, 0.1 to 1. Minor amounts of uranium, bauxite, tungsten, petroleum, and natural gas were also produced.

Czechoslovakia's mineral output in 1963 was no greater than that in 1962, despite government efforts to raise efficiency of existing facilities and improve labor productivity. The winter was severe, and completion of many mines and plants was delayed. For example, certain coal mines designed to add more than 1 million tons of output annually to the national total and a 215,000-ton coal beneficiation plant were not completed. Only one-third of the 382,000 kilowatts of new electirc power capacity planned went into operation during 1963.

The mineral industry contribution to the 1963 gross national product was about 7 to 8 percent, with coal and iron and steel furnishing the predominant share. Imports and exports of mineral products were significant in the total trade of Czechoslovakia. Mineral raw materials, headed by iron ore, nonferrous ores and metals, and petroleum, comprised about one-half of total imports. Mineral and metal exports consisted largely of exports of semifinished products, but these comprised only about one-fourth of total exports. Czechoslovakia's coal-mining and iron and steel industries occupied an important position in Eastern Europe.

Few important mineral developments occurred. Most government effort was centered on improving existing facilities and introducing new equipment. Low productivity held back fulfillment of certain plans in mining and refining of metals. Shortage of electricity seriously affected mineral output.

The coal industry was developing new sources in 1963, but the overall output target was not achieved. Introduction of new auto-

[1] Foreign mineral specialist, Division of International Activities.
[2] Chief specialist, East Europe-Far East, Division of International Activities.

Digitized by Google

mated equipment met with some success, although coal-mining productivity was still far below U.S. and Western European standards.

Construction of the large iron and steel plant near Kosice continued. A new magnesite mine, Podrecany in Slovakia, of unknown capacity was being developed for the needs of the refractory magnesia plants at Kosice.

A petrochemical plant was commissioned at Valaske Mezici in 1963. The equipment used was from Czechoslovakia and East Germany. During the initial stage, production will be confined to aromatic derivatives such as ethylene, benzene, xylene, and toluene.

SOURCE MATERIAL

Information on activities in Czechoslovakia is somewhat limited. Czechoslovakia publishes a yearbook that contains statistics on the production of minerals and other information pertaining to the minerals industry; however, this book does not give complete coverage on production or trade. Data on trade in minerals were compiled principally from official sources in the U.S.S.R. and partly from statistics in the yearbook. Other information was provided by the technical press and dispatches from the U.S. Embassy in Prague.

PRODUCTION

The condition of the industrial economy in Czechoslovakia in 1963 was reflected to a large degree by the output of principal mineral and metal products such as coal and iron and steel. Coal production was below expectations; steel output, which accounted for one-tenth of the nation's gross industrial product, was about the same as in 1962. Data on production of nonferrous metals have not been officially reported, but output value in 1963 was about 1 percent of the gross industrial product. Cement production declined. During the 5-year span of 1959–63, almost all of the branches of the mineral industry that have consistently reported output attained significant increases.

[1] In addition to reported commodities, Czechoslovakia is known to produce (figures represent 1963 production estimates, in metric tons) antimony 1,600; lead, mine 13,500, smelter 14,000; tin, mine 200; 725 76-pound flasks of mercury were also produced.
[2] Estimate.
[3] Data not available.
[4] Information not available in time for inclusion in commodity chapter of volume 1.

TRADE

Mineral trade, particularly imports, was of great importance to Czechoslovakia in 1963, as in the past.

Mineral and metal exports represented about one-fourth of all exports in 1963. The most significant products exported included rolled steel products, pipes, and coke. Czechoslovakia is a manufacturing country, relying mainly on foreign raw materials in order to make semifinished and finished products for consumption and export.

Czechoslovakia's mineral imports, consisting mainly of raw materials, were worth approximately 7 billion koruna [3] in 1963, half of all imports. Most of the country's requirements for nonferrous metals, iron ore, crude petroleum, and bituminous coal were met by imports.

Official Czechoslovakian trade statistics do not reveal the destination of exports or the origin of imports, but comparison of these data with the trade statistics of the U.S.S.R. shows the importance of the U.S.S.R. as a trading partner. Moreover, U.S.S.R. statistics show

[3] US$1 equals 7.2 koruna.

COMMODITY REVIEW

METALS

Iron and Steel.—Iron and steel has long been the leading branch of Czechoslovakia's mineral industry. The long-range plan is to more than double the 1963 output of about 7.6 million tons of steel ingot when plants now under construction are completed. The iron-ore-supply picture showed no great improvement during 1963, and it is estimated that two-thirds of the iron ore came from the U.S.S.R. Continued and perhaps even greater dependence upon Soviet iron ore, manganese ore, and pig iron seems probable when the new Czech facilities are completed.

Nine iron and steel plants were operating during 1963, and some modernization of facilities and increase in pig iron capacity took place.

758-002—65——27

Digitized by Google

The East Slovakian iron and steel works near Kosice entered the fifth year of construction; this plant will eventually have an annual steel-ingot capacity of 7 million tons, through the installation of six large oxygen converters and other furnaces. The plan was to complete a cold-rolling mill in 1963, followed by the construction of blast furnaces, steel furnaces, and additional rolling mills. Planned completion date of the whole facility is not known, but a large steel complex is clearly in the making. The plant will probably be supplied with Soviet iron ore; new Soviet-gage railroads are reportedly being built.

Nonferrous Metals.—Activities in nonferrous metals were kept secret as usual. The only known Czechoslovakian aluminum plant, at Ziar, with an annual capacity of possibly 50,000 tons, continued to depend almost entirely on Hungarian bauxite. Lead imports appeared to be somewhat larger than the estimated 1963 local output of 13,500 tons of refined lead. Several hundred tons of tin and about 725 76-pound flasks of mercury apparently were produced during the year. About 5,000 tons of copper was produced in 1961, equivalent to about a third of the imports from the U.S.S.R. in that year and about a fourth of the imports in 1962. The Czechs have a well-established antimony industry of some world consequence and were involved in negotiations to assist Bolivia in building an antimony plant. However approval of this assistance program had not been given by the Bolivian Government at yearend.

NONMETALS

Czechoslovakia remained virtually self-sufficient in most nonmetals in 1963, and few developments of consequence occurred. Development of the new magnesite mine at Podrecany and improvements made in many of the 16 operating cement plants made nonmetals one of the most successful branches of the Czech mineral industry in 1963.

MINERAL FUELS

Coal.—Bituminous and brown coals and liquid fuels derived from brown coals accounted for 85 to 90 percent of the Czechoslovakian energy supply in 1963. Coal mining was greatly modernized during the year by the installation of many new machines, conveyors, and facilities which gradually became standard equipment. In the Ostrov-Karvina area, the country's foremost bituminous coal center, several new shafts were put into operation, although capital construction was behind schedule. Ostrov-Karvina has the best coking coal in Czechoslovakia.

The Mostov-Sokolovo basin provided 90 percent of the country's brown coal. To meet production targets, Sunday work became normal practice. Also, workers from other segments of the nation's industrial labor force spent their vacation working in the brown coal mines.

Some trace metal production is linked to the Czech coal industry. Germanium was recovered from certain coal-burning plants using Sokolovo brown coal and bituminous coal from Kladno and Plzen. Gallium recovery from coals also was considered.

Petroleum.—Crude oil production remained unimportant. Refined petroleum output, while much larger, was still a minor part of the

Digitized by Google

energy supply. Four regular oil refineries and one synthetic-oil-from-coal plant, with reported aggregate daily crude input capacity of about 65,000 barrels (roughly 8,800 metric tons), operated during the year. Crude oil imports came mainly through the Druzba pipeline from the U.S.S.R.

The Mineral Industry of Denmark

By Charles D. Hoyt[1]

DENMARK, a small country with fewer natural resources than most other countries, continued the expansion of its economy during 1963. Lacking nearly all mineral resources except some nonmetallics and construction materials such as limestone, chalk, clays, diatomaceous earths, and building stone, the country continued to depend on imports for nearly all its raw materials and fuels. Despite this absence of an indigenous natural resource base, the country, through advanced technology and a skilled labor force, combined with an ideal location, continued to expand its output of industrial goods of all types. In 1963 the country's total exports consisted of slightly over 40 percent manufactured items, which were almost entirely produced from imported raw materials, and 40 percent agricultural products, which also were highly dependent on imports (fertilizers) for continuance and expansion of the high degree of productivity.

Within the mineral and mineral-processing fields the only significant event during 1963 was the completion and startup (September–October) of the country's second major refinery, owned by a U.S. firm, the Gulf Corp.

GOVERNMENT POLICIES AND PROGRAMS

Mining activities in Denmark continued to be regulated by law No. 181, May 1950, which provides a State monopoly of all mineral deposits that were not exploited prior to February 23, 1932. Additional mineral legislation was passed on July 16, 1962, which specifically refers to petroleum exploration and exploitation. The May 1950 law allows the Danish Government to grant concessions, not exceeding 50 years, for prospecting for and extracting raw materials.

Under the 1950 mining law, an exclusive concession was granted to the Danish-American Prospecting Co. (owned by the Gulf Oil Corp.) in August 1950 for the prospecting and extraction of all minerals for 50 years. A condition of the concession was that production must begin within 10 years of the initial agreement. In 1957, the Standard Oil Co. of New Jersey took over the Gulf concession rights; however, nothing of significance was discovered and presumably the concession expired in August 1960 since there was no production within the prescribed 10 years. Under the same mining law, a 50-year conces-

Digitized by Google

sion was granted for prospecting and mining molybdenum and certain other minerals in Greenland.[2]

PRODUCTION

The principal change in Denmark's modest mineral industry output has come in the fuels field with the rapid expansion of petroleum refining. Compared with 1962, production of refined products during 1963 increased by over 52 percent to 15 million barrels. This was because Denmark's second major refinery came on stream in October 1963. There were no appreciable changes in the output of the iron and steel industry. Nonmetals registered a decrease of about 7.5 percent in the production of portland cement and an expansion in phosphate fertilizer output. Other changes in the production pattern were minimal.

TRADE

Since Denmark has no indigenous sources of petroleum, it must import its requirements as either crude oil for processing or finished petroleum products. While output of petroleum products increased by almost half in 1963 with the opening of the new refinery, crude imports were increased by over 40 percent to provide the throughput for the new installation.

As in previous years, Denmark depended on imports for the bulk of its mineral-resource-based needs in 1963. In addition to a large petroleum trade, significant quantities of iron and steel semimanufactures, fertilizers, and salt were imported. Lesser tonnages of practically all other mineral commodities also were imported. Denmark's principal exports in 1963 continued to be cement, refined cryolite, and building materials.

The principal changes in the trade pattern for 1963 were in the petroleum industry. In the nonmetallics and metals area, there were no really noteworthy differences in the trade volume. As in past years, West Germany, the United Kingdom, and Sweden were the principal trading partners for Denmark.

TABLE 2.—Exports of metals and minerals

COMMODITY REVIEW

METALS

Iron Ore.—The only ferrous mineral in the country is a low-grade (40 percent iron) bog iron which is a spongy hydrated oxide of iron. The primary use of this material has been for gas purification. Output for 1963 declined to about 85,000 tons; and estimated two-thirds of the total production was exported, principally to the United Kingdom, with lesser amounts to West Germany.

Digitized by Google

Iron and Steel.—In 1963 the country's iron and steel requirements (1.1 to 1.2 million tons annually in recent years) continued to be supplied principally by imports. About three-quarters of the country's needs were provided by imports, and the remainder was supplied by Denmark's only steel producer, the Danish Steel Works, Inc. (Det Danske Staalvalsevaerk, A.S.). Ingot output in 1963 by this plant reached 316,100 tons, and rolled-steel production increased to about 270,000 tons. Output has approximately doubled since 1954. Iron and steel output at the Danish Steel Works was based principally on domestically generated scrap which originally was imported in the form of steel products, ships, machinery, etc.

The output of the country's single pig iron producer, Norden Cement-Iron Combine (Cement-Jern Konsortiet Norden), was also based on scrap. This metal was consumed primarily for iron castings within the country's large foundry industry, and only limited quantities were used for steel production. The country also has imported appreciable tonnages of pig iron (75,000 to 110,000 tons in recent years) to satisfy domestic needs. Preliminary figures indicate that pig iron imports for 1963 were slightly over 80,000 tons.

Nonferrous Metals.—All nonferrous metals must be imported, and total imports (in all forms including scrap) in the past few years have been about 85,000 tons annually. Preliminary import statistics for 1963 show that major nonferrous imports amounted to almost 79,000 tons, distributed as follows: copper 32.5 percent; aluminum 23.5 percent; lead 23.5 percent; zinc 19.0 percent; and tin 1.5 percent.

Only two significant producers refined and further processed nonferrous metals. The first of these was the Northern Cable and Wire Works, Inc. (A. S. Nordiske Kabel og Traadfabriker), whose output of cables and electric wires in recent years has been 31,000 to 35,000 tons annually. Semimanufactures of nonferrous metals also have been produced, along with iron wire products. In late 1963 it was reported that this company had joined with the United Kingdom aluminum producer, Aluminium, Ltd., to form a new company, Aluminord, A.S. Existing rolling facilities at one of the Northern Cable and Wire Works operations will be used for the venture. Efforts will be made to find new uses for aluminum in the packaging and construction industries. Plans called for doubling the present aluminum-rolling capacity of the Danish plant, which in 1963 was 12,000 tons annually. No schedule was announced for this proposed expansion. Aluminum, Ltd., was slated to provide the necessary capital, primary aluminum, and technical assistance for the new company.

The other major nonferrous firm was Paul Bergsøe and Son, which produced solders, type metals, babbitts, and a wide variety of lead, copper, tin, and antimony alloys. The firm has operated internationally, and there were affiliated companies and operations in Sweden, Norway, Finland, the United Kingdom, and Brazil. These associated companies operated under the general name Scandinavian Metal Corporation. Total output of the three Paul Bergsøe and Son Scandinavian plants has amounted to about 76,000 tons annually in recent years.

NONMETALS

Denmark's output of nonmetals increased in 1963. Most of the nonmetallics produced domestically were used within the construction field. Over 3 million tons of limestone was produced for the manufacture of cement (1.5 million tons output in 1963), and over 200,000 tons of a clayey diatomaceous earth (moler) was mined in 1963. About one-half the moler output was exported in bulk form, mainly to West Germany and the United Kingdom. The balance was used to manufacture refractory bricks and other refractory materials in Denmark; these also were exported, but to a great number of countries. The country lacks most nonconstruction nonmetallics. Salt, sulfur (pyrites), and fertilizers are consumed in moderate quantities and must be imported, along with most other nonmetals.

MINERAL FUELS

Coal, Coke, and Peat.—The bulk of the country's solid fuel needs were supplied by imports, practically all of which came from other European countries. Preliminary trade figures for 1963 show total solid fuel imports of almost 6 million tons (75 percent coal, 25 percent coke), practically the same as in 1962. Poland has been the principal source of coal and West Germany the chief supplier of coke, with the United Kingdom the most important secondary source of both coal and coke.

Domestic output of solid fuels was limited to production of low-grade lignite (output, about 2 million tons annually, goes almost entirely to powerplants) and to a small amount of peat, used principally as domestic fuel in rural areas. The reserves and quality of the lignite are very poor, and therefore there is practically no basis for any significant expansion within the domestic fuels industry.

Petroleum.—During 1963 Denmark continued its surge of building additional refinery capacity designed to supply rapidly expanding Danish and other Scandinavian markets. In the past few years Danish per capita oil consumption (1.55 tons in 1962) ranked second only to Sweden in Scandinavia and was among the highest in Europe. Total domestic sales in 1962 exceeded 7 million tons, compared with about half this amount in 1957; the average annual increase for this period was about 12 percent. It has been estimated that petroleum products currently supply 62 to 63 percent of the country's total energy requirements and that by 1970 this dependence on petroleum and its derivatives will have increased to about 70 percent. At this time the domestic consumption is expected to reach 10 million metric tons, which would be an almost trebling of consumption over 14 or 15 years.

Within the past 4 years major oil companies have started building large-scale refineries in Denmark, based on past growth rates and potential domestic and other Scandinavian markets. The first major refinery, built by the Tidewater Oil Company interests, was completed in 1961 at a cost of over $24 million. The refinery is at Kalundborg and had a refining capacity of 1.5 to 1.7 million tons (20,000 barrels per day crude throughput) in 1963. During 1962 this refinery was sold to Esso (New Jersey Standard) which planned to more than double the 1963 capacity. Esso supplied about 27 percent of the total

Digitized by Google

Danish markets in that year. Tidewater retained processing rights for 900,000 metric tons of refining capacity annually from the existing plant.

Denmark's second major refinery officially went on stream in early October 1963. This new refinery, at Stignaes in southwest Zealand, is owned by the Gulf Oil Corporation and was this corporation's first independent venture in Europe. The 1963 rated capacity was 30,000 barrels per day crude throughput. It is anticipated that one-third of the new refinery output will supply the 10 percent of total Danish requirements that have been provided by Gulf through imports; the balance will be exported to Sweden, Scandinavia's largest consumer of petroleum products. A third major refinery, under construction in late 1963 at Fredericia on the east coast of the Danish mainland, is to be owned by the Shell Oil Co. The facility will have a rated capacity of about 2 million tons per year upon completion, which is expected to be in late 1965. Shell interests supplied about 13 percent of total Danish markets in 1963.

Even when the third major refinery in Denmark is completed in late 1965, refinery capacity will not be equal to the current domestic needs of the country. Denmark still will require significant imports of petroleum in all forms to supply the country's rapidly expanding markets.

The Mineral Industry of Finland

By Anton W. T. Wei [1]

OUTPUT of minerals and metals in Finland increased in 1963, continuing the general upward trend of the past decade. Commodities of world significance included vanadium (about 10 percent of world output) and ilmenite concentrate (about 4.5 percent). However, because of the moderate tonnages of total world output, these two commodities occupied only relatively minor positions in Finland's mineral industry. According to the Central Statistical Office, the country's total 1963 mineral output was 8 percent above that of 1962, and basic metal production increased 4 percent. As in the past, Finland did not produce any mineral fuels in 1963. Excluding refined petroleum, the country's total value of mineral production in 1963 was roughly the equivalent of US$130 million. Refined petroleum output, all from imported feed stock, totaled 15.5 million barrels during the year.

Active geologic exploration and development of new mineral areas and existing facilities took place throughout 1963. Results of preliminary investigation and test drillings by the Geological Research Institute in the Nivala area were encouraging, with total reserves estimated at 5 million tons of nickel-copper ore averaging 0.7 percent nickel, 0.26 percent copper, 3.5 to 10 percent sulfur, and minute fractions of platinum. A final report on this exploration project was being prepared for submission to the Ministry of Commerce and Industry. It was reported that the eventual exploitation of this deposit would probably be assigned by the Ministry to Outokumpu Oy, a State-owned enterprise which operates the country's nonferrous metal and pyrite mines.

According to newspaper reports during the year, the Lohjan Kalkki Oy would begin mining a large apatite deposit near the village of Kuuslahti, 5 kilometers east of Siilinjärve in east-central Finland. Test drilling during the past 4 years had uncovered deposits reportedly about 12 kilometers long and 700 meters wide. While the ore bodies seemed rich enough to justify exploitation, their location far from the processing industry in Oulu would mean high transportation costs. In the meantime, the Typpi Oy fertilizer factory in Oulu, which went into operation in March 1963, established a new plant for the manufacturing of rare-earth oxides. At full capacity, the plant was reportedly capable of producing 100 metric tons of oxides annually.

Elsewhere, metallurgical investigation was continuing on the chromite ores of Kemi. These ores were being tested at the Pori

[1] Physical scientist, Division of International Activities.

Digitized by Google

testing plant, where various procedures were being tried in an attempt to improve the chromium-iron ratio in the concentrate. Exploration by driving shafts and by diamond drilling was carried out on the Kolari iron deposits. At yearend, no decision had been reached regarding the exploitation of these deposits.

GOVERNMENT POLICIES AND PROGRAMS

There did not appear to be any specific program to expand the government's role in the mining and metallurgical industry. However, the implemented and planned expansions of State-owned facilities in iron ore, iron and steel, petroleum, and nonferrous metals had the same effect.

In 1963, government-owned companies already were the only operators in the petroleum and nonferrous areas. Upon completion of new facilities as planned during the year, the government steel plant was to become the largest single producer and dominant in the field.

SOURCE MATERIAL

Information on production and significant developments in Finland's minerals industry is derived principally from foreign service dispatches of the U.S. Embassy in Helsinki. Data on mineral imports and exports are obtained from official Finish trade publications.

PRODUCTION

Of the total value of the minerals and metals produced in Finland in 1963, excluding refined petroleum, semimanufactures of iron and steel accounted for nearly 45 percent. Hydraulic cement and metallic copper each accounted for about 20 percent, and metallic nickel and lead concentrates each about 4 percent. Of the rest, the more significant items included vanadium pentoxide, lime, pyrite, and ilmenite. Although mineral output generally increased in volume in 1963 over that of previous years, a notable exception occurred in lead production, which fell to less than half the 1962 level. The year saw the first production of sulfur, which was produced in significant quantities, from the new Kokkola pyrite-processing plant.

[3] Final figure; supersedes figure given in commodity chapter, volume I.

TRADE

The overall pattern of Finland's mineral trade in 1963 remained relatively unchanged. Value of mineral and metal imports totaled approximately 1.4 billion new marks (1 new mark=US$0.3125), representing roughly 36 percent of the country's total imports for the year. Mineral and metal exports totaled about 100 million new marks, or less than 3 percent of the country's overall exports in 1963.

COMMODITY REVIEW

METALS

Iron Ore.—Expansion of Finland's iron ore mining industry was advanced in 1963. Preparatory work continued on the Raajärvi iron mine in northwest Finland by Otanmäki. The mine was scheduled to start operation in the summer of 1964, and ore would be processed primarily by Rautaruukki Oy in its new facilities at Raahe. Excluding Finland's pyrite, which is used eventually as an iron raw material, Raajärvi will be the country's fourth producer of conventional iron ore. The Kolari iron deposit was explored by driving shafts and diamond drilling.

[1] Countries of origin are not reported for 1962 and 1963.

Iron and Steel.—Oy Vouksenniska Ab, a privately owned steel company, initiated in 1963 a relatively extensive 2-year development program covering its plants at Imatra and Turku (Abo). The equivalent of US$5 million was allocated to replace an old blast furnace at Turku with one of modern design, capable of producing 120,000 tons of pig iron annually, and to modernize the steel mill at Imatra. This modernization will include new hardening and tempering furnaces for continuous-process heat treatment of steel. Orders for most of the

Digitized by Google

heavy machinery and equipment had been placed with West German suppliers; the balance was to be supplied by Swedish or local firms.

Construction of the 350,000-ton-annual-capacity blast furnace and sintering plant at Raahe by the State-controlled company of Rautaruukki Ab continued throughout 1963. These initial facilities, supplied by the U.S.S.R., were scheduled to begin operations in early 1964, with iron ore supplied largely by the State-owned Otanmäki Oy. As of 1963, expansion plans included the addition of a melting shop, oxygen plant, and plate mill. The melting shop was to consist of two 50-ton Linz-Donawitz converters and three single-strand continuous-casting machines with an initial annual production of 400,000 tons of steel for the plate mill. Upon completion of these facilities, Rautaruukki Ab would become the largest steel plant in the country, surpassing Vouksenniska Ab. Construction plans also allow for the addition of a third converter and an additional continuous-casting machine at a later date.

Nonferrous Metals and Pyrites.—The State-owned firm of Outokumpu Oy remained the sole nonferrous metals and byproduct pyrite producer in Finland. At its Outokumpu mine, which accounted for over two-thirds of the country's total mine copper output in 1963, pebble mills were substituted for rod mills in the concentrating plant. In its first full year of operation, the new Pyhäsalmi mine produced about 4,300 tons of copper in concentrates, 286,800 tons of pyrite concentrates, and 18,400 tons of mine zinc. The balance of Finland's 1963 mine copper output was contributed by the Ylöjärvi, Vihanti, and Kotalahti mines; Vihanti was the country's major zinc producer and Kotalahti was the only producer of mine nickel.

In its first year of operation, the Kokkola plant of Outokumpu Oy treated about 230,000 tons of pyrite concentrate from Pyhäsalmi, producing 38,000 tons of sulfur and 152,000 tons of pyrite sinter. The plant also generated about 268 million kilowatt-hours of electricity from the waste heat of the metallurgical facility. The research section at Harjavalta, Finland's only copper smelter and nickel refinery, accomplished the separation of cobalt from nickel. Reports indicate that tests were being conducted to recover the cobalt. In the meantime, expansion and modification begun in 1962 at the nearby Pori copper refinery were practically completed during 1963. This refinery produced all of Finland's electrolytic copper, which was oxygen-free high-conductivity material, as well as refined gold, silver, and selenium.

In addition to investigations of the Nivala copper-nickel deposit, preparatory work was carried on at the Kaavi copper and pyrite deposit. However, no definite plans had been made for the start of actual mining.

MINERAL FUELS

Coal and Coke.—Lacking domestic coal production, Finland's demands for this fuel were supplied by imports. Total coal consumption of 2,175,000 tons in 1963 was 1.2 percent less than the 2,202,000 tons consumed in 1962. The marked increase in coal consumption for electric power generation, and the lesser increases in use as locomotive fuel, in the paper and woodworking industry, and for gas and coke manu-

Digitized by Google

facturing were more than offset by the sharp decline in other minor industries where a fuel oil replaced coal in significant quantities. Coal used for space heating also showed a small decline in 1963.

Approximately two-thirds of the country's consumption of coke in 1963 was supplied by direct imports; the balance was produced domestically from imported coal. Total coke consumption in 1963 was 484,000 tons, compared with 528,000 tons in 1962. The marked decrease of coke used for space heating in 1963 was offset slightly by the minor increase of coke consumed for metallurgical purposes.

Petroleum.—Owing to the expansion program completed in late 1962, the annual input capacity of the Neste Oy Naantali plant, Finland's State-owned and sole oil refinery, was raised from 1.2 to 2.4 million tons. Output of refined products increased to more than 15.5 million barrels, compared with 10 million barrels in 1962. Anticipating continued growth of Finland's consumption of petroleum products, Neste Oy was planning to build oil storage facilities, a harbor, and a second refinery near Porvoo, about 48 kilometers east of Helsinki. Construction of six storage tanks of about 190,000 barrels each began in March 1963, on the site at Sköldvik, which would bring the company's total storage capacity to about 6.3 million barrels. As of early 1963, no final decision had been made on the construction schedule of the refinery, but according to company calculations the consumption of petroleum in the Helsinki economic area alone would justify the erection of this refinery before 1970.

The possibility of the eventual construction of a gas and oil pipeline from Leningrad to Helsinki was also in the news in early 1963. According to a Soviet spokesman, the building of this overland pipeline has been agreed upon in principle between the governments of Finland and the U.S.S.R. If built, the line would be a continuation of the Soviet Leningrad line, scheduled for completion in 1965.

The Mineral Industry of France

By L. Nahai [1]

FRANCE in 1963 ranked third in world production of iron ore, fourth in aluminum, fifth in bauxite, gypsum, and potash, and sixth in cement and in iron and steel. In Western Europe, France was the leading producer of iron ore, bauxite, aluminum, sulfur, and some quarry products and supplied some of the requirements of this area for these commodities as well as for potash.

The national product of France, excluding services, grew in real terms in 1963 by about 5 percent. Sufficient data on mineral production in 1963 are not available to determine whether the mineral industry as a whole had the same growth rate. The substantial drop in production of solid fuels and iron ore may not have been sufficiently compensated by increases in production of petroleum, natural gas, and sulfur to insure a total increase comparable to that of the national product.

Value of mineral output in 1962 was about US$1,590 million [2] including: Solid fuels US$704 million, quarry products US$344 million, metallic minerals US$241 million, nonmetallic minerals other than quarry products US$142 million, and petroleum and natural gas US$106 million. The remainder was accounted for by a value assigned to the uranium mineral output. The total value was equivalent to 2.5 percent of the gross domestic product (production intérieure brute) of US$64,000 million in 1962 prices.

France continued to be an important consumer of minerals. In the case of nonferrous metals (with the notable exception of aluminum), the country remained partially or totally dependent on foreign sources. French smelting facilities were inadequate to meet even domestic needs for most of these metals, notably copper, for which France has no ore smelters. Many industrial minerals such as asbestos, magnesite, and mica, as well as crude phosphate, must also be imported.

In 1962, the mining industry, other than quarrying and slate production, employed 256,000 workers, of which 204,000 were in coal and lignite mining, 26,000 in iron, and 12,400 in potash mining. Approximate employment in quarry and slate mining was 90,000 and in cement and lime plants 13,500. Petroleum exploration, production, and refining employed 27,000. Among metallurgical plants, the iron and steel industry employed about 131,000, the ferroalloy industry 4,500, and the nonferrous metal industry, including secondary metal producers, 9,500. The total of 531,000 workers was about 1 percent of France's industrial labor.

Starting in 1946 France has had a number of economic development plans, the current or fourth plan spanning the period 1962–65. The successive plans have set production objectives for the basic sectors of the economy, including the mineral producing and processing sector. Although execution of the plans has not been mandatory on industry and other enterprises, the government has provided financial assistance and guidance to such enterprises as have been willing to carry out their expansion program within the objectives of the plan. French industry and agriculture have been very cooperative in this endeavor.

PRODUCTION

Overall French industrial production in 1963 increased by 4.9 percent. Petroleum had the greatest growth rate in the mineral industry. Because of a 7.5 percent increase in natural gas production, sulfur recovered from natural gas increased by 10.5 percent. Nonferrous production increased 7.2 percent, primarily because of increases in aluminum, lead, and zinc production. In response to the rising industrial output, consumption of iron and steel increased by 4 percent, but the increased requirements were met mainly from imports and stocks so that the 1.8-percent rise in iron and steel output did not parallel the rise in industrial activity or steel consumption.

Decline in the index of metallic ore production resulted mainly from lower iron ore output, partly as a result of a strike and partly because of reduced shipments to the European Coal and Steel Community. Solid fuel production declined because of a strike.

Official production data on quarry products and construction materials for 1963 are not available. Increase in public works and construction must have helped maintain the increasing trend in production of materials used by this industry. Monthly averages for a number of items, including lime and cement, increased. However, production of sand and gravel from pits declined slightly. The severe winter adversely influenced output, with production in the first quarter equal to only 13.3 percent of the total for the year.

A 10.3-percent rise in production of salt paralleled that of the chemical industry, but potash production remained at about the same level as in 1962.

TABLE 1.—Index of industrial production

(1959 base = 100)

	1962	1963	Variation 1963–62 (percent)
All industrial production including construction	121	127	+5.0
All industrial production excluding construction	122	128	+4.9
Metal ore mining	109	95	−12.8
Mining and preparation of miscellaneous minerals	117	117	
Metal production	116	118	+1.7
Metal working	125	130	+4.0
Building and public works	116	124	+6.9

[2] Hydrated and calcined alumina are successive stages of alumina production and are not to be added.
[3] Arsenic content of final products.
[4] Excludes ferromolybdenum, ferrotungsten, and ferrovanadium, where production data are for contained metals.
[5] Lead content.
[6] Includes distilled zinc from scrap and residues
[7] Estimate.
[8] Shipments.

TRADE

Imports and exports of tabulated minerals and metals in 1963 were equivalent to 28.7 and 17.6 percent of total imports and exports, respectively. Iron and steel, including scrap, ranked first in export values followed by petroleum products, accounting for 9.8 and 3 percent, respectively, of all exports of France. Mineral fuels were the largest imports both in tonnage and value, accounting for 57.2 percent of mineral and metal imports and 16.5 percent of all imports. For petroleum, France had an adverse trade balance of about US$707 million.[3]

In 1963, 38.3 percent of all exports of France were to the other countries of the European Economic Community (EEC)[4] and 54.5 percent to countries of the EEC and the European Free Trade Association (EFTA)[5] combined. The corresponding import figures were 35.8 percent from the EEC and 47.9 percent from the EEC and EFTA combined. For the minerals and metals tabulated, France's exports to the EEC were 48.18 percent and to the EFTA 17.5 percent of the total. For the same commodities, imports from the EEC were 36.7 percent and from the EFTA 6.2 percent of the total.

[6] According to Élements Statistiques, Activité de l'Industrie Pétrolière, 1963, the adverse balance was US$683 million. The discrepancy results from the fact that this source uses general export figures which include re-exports of refined products.
[4] The EEC includes Belgium, France, Italy, Luxembourg, the Netherlands, and West Germany.
[5] The EFTA includes Austria, Denmark, Norway, Portugal, Sweden, Switzerland, and the United Kingdom.

Coal, coke, and other solid fuels	22,785	463,764	1,069	16,851
Petroleum:				
Crude	43,258	821,917		
Refinery products	4,608	140,916	7,736	249,770
Natural and manufactured gas	214	9,252	420	9,488
Total	70,865	1,435,849	9,225	276,109
Grand total	89,206	2,507,986	48,647	1,452,503

[1] The total which includes cast iron pipe and fittings and old rails is slightly different from total calculated from ECSC data.
[2] Including copper matte, nickel matte, speiss, etc., silver and platinum ores, uranium and thorium ores.
[3] Of the total 205,900 was bauxite.
[4] Includes lime and cement.
[5] Data not available.

Source: United Nations. Commodity Trade Statistics, 1963. Statistical Papers, ser. D, v. 13, Nos. 1–12, pp. 2155–2282.

French exports of iron and steel to EEC countries which totaled about half of mineral exports to all destinations and exports of iron ore, sulfur, and potash were the principal minerals traded between France and the rest of the EEC. Among the EFTA countries, Austria, the United Kingdom, and Switzerland were important markets for French potash and other fertilizers. Switzerland was the largest market for petroleum products, and the United Kingdom was the third largest after Algeria. France also shipped 36.6 percent of its sulfur to EFTA countries with the United Kingdom as the largest market.

Iron and steel, solid fuels, and some nonferrous metals (copper, lead and zinc) were France's principal imports from its Common Market partners. Of imports from Algeria, valued at US$571 million, petroleum accounted for US$306 million. Phosphate rock and metallic ores imported from Morocco accounted for 18.7 percent of the value of all imports from that country, which totaled US$209.8 million.

France's export in 1962 to the United States comprised iron and steel, aluminum, chromium, cobalt, fluorspar, and potash. Principal imports from the U.S. were coal, boron minerals, and titanium.

TABLE 4.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962 [1]
Metals:			
Aluminum:			
Alumina, calcined	138,333	167,745	Spain 88,436; Switzerland 62,569; Poland 15,031.
Bauxite	256,312	266,628	West Germany 153,091; United Kingdom 102,734; total EEC 158,699.
Ingots	123,807	105,184	Belgium-Luxembourg 39,182; United States 30,463; West Germany 11,381; Netherlands 6,705; Italy 5,078; Argentina 2,513; total EEC 62,846.
Scrap	2,237	7,317	Italy 3,704; West Germany 3,312; total EEC 7,283.
Semifabricated	26,718	29,201	Belgium-Luxembourg 5,581; West Germany 2,255; Italy 1,945; Denmark 1,172; total EEC 10,969.
Antimony	152	82	Switzerland 34.
Beryllium, including semifabricated	2	3	United Kingdom 2.
Bismuth	65	45	United Kingdom 44.
Cadmium	24	22	Italy 6; Spain 5.
Chromium:			
Chromite ore	10	61	EEC 41.
Metal	416	192	United States 150.
Cobalt	231	443	United States 365.
Copper:			
Ores and concentrates	685	----------	
Matte	2,700	428	Italy 189; West Germany 158; total EEC 408.
Scrap	18,687	22,692	Belgium-Luxembourg 7,651; Italy 7,192; West Germany 4,174; total EEC 19,062.
Ingots, including alloys	12,906	15,514	West Germany 6,521; Belgium-Luxembourg 5,676; Italy 2,798; total EEC 14,066.
Copper:			
Refined	1,579	2,477	West Germany 1,309; Italy 648; total EEC 2,309.
Semifabricated	22,666	17,731	Switzerland 3,324; Morocco 1,679; West Germany 1,271; total EEC 4,468.
Gold:			
Re-export ---troy ounces	68,224	27,489	Netherlands 10,513; West Germany 7,555; Switzerland 3,987; Belgium-Luxembourg 3,762.
All forms ---do	55,428	32,504	Salvador 8,925; Algeria 6,623; Netherlands 5,401.
Iron:			
Ore ---thousand tons	25,855	25,683	Belgium-Luxembourg 16,265; West Germany 9,070; United Kingdom 326; total EEC 25,336.
Pyrite cinder ---do	402	361	West Germany 294; United Kingdom 46; total EEC 315.
Scrap ---do	1,161	1,190	Italy 1,112; West Germany 35; Belgium-Luxembourg 12; total EEC 1,188.
Pig iron, spiegeleisen, and high carbon ferromanganese. ---do	415	380	Belgium-Luxembourg 203; West Germany 86; Italy 40; United States 39; total EEC 330.
Ferroalloys except high carbon ferromanganese. ---do	66	53	(3).
Ingots, blooms and billets ---do	270	168	West Germany 1,322; Italy 572; Switzerland 304; Belgium-Luxembourg 201; United States 188; Netherlands 135; total EEC 2,230.[3]
Rolled steel ---do	5,440	4,833	
Cast iron pipes and other ---do	117	118	(3).
Lead:			
Ores and concentrates	8,501	4,914	Belgium-Luxembourg 4,108; total EEC 4,504.
Scrap	1,669	7,551	Italy 7,415; total EEC 7,551.
Pig	6,178	5,484	Switzerland 3,854; West Germany 719; total EEC 1,227.
Semifabricated	1,166	770	Norway 210; Algeria 148; Tunisia 39; Morocco 36.
Magnesium:			
Scrap	76	58	West Germany 20.
Ingots	19	5	(3).
Wrought	10	19	Israel 11.
Manganese:			
Ores and concentrates ---thousand tons	768	1,622	Italy 856; Switzerland 285; Netherlands 228; total EEC 1,161.
Metal	30	20	(3).

TABLE 4.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962 [1]
Metals—Continued			
Mercury—76-pound flasks	319	319	Upper Volta 174; Algeria 58.
Molybdenum, all forms	4	11	(2).
Nickel:			
Matte	51	412	West Germany 322; Italy 8; total EEC 333.
Scrap	1,665	1,095	United Kingdom 443; Italy 378; total EEC 630.
Ingots	3,334	5,351	USSR 3,009; West Germany 465; total EEC 652.
Anodes	264	304	West Germany 124; Italy 52; Spain 35; total EEC 196.
Semifabricated	478	680	Spain 157; Netherlands 98; Belgium-Luxembourg 59; total EEC 309.
Palladium group—thousand dollars	5,316	54	Belgium-Luxembourg 14; Switzerland 13; United States 7; Brazil 6.
Platinum—troy ounces	23,920	31,861	Netherlands 11,028; Brazil 5,498; Switzerland 5,337.
Silver:			
Crude—thousand troy ounces	932	3,922	United States 2,443; Switzerland 707; Spain 418.
Semifabricated—do	1,125	1,222	Mainly to Netherlands.
Thorium and uranium ores and concentrates.	679	----------	
Tin:			
Ores and concentrates	1,559	471	Spain 382; Netherlands 78.
Scrap	78	41	United Kingdom 34; West Germany 6.
Ingots	178	158	Switzerland 43; Netherlands 31.
Semifabricated	185	133	Tunisia 53.
Titanium, vanadium, molybdenum and zirconium ores and concentrates.	743	521	West Germany 411; Netherlands 50; total EEC 469.
Titanium, metal	14	4	(2).
Tungsten:			
Ore and concentrate	395	486	West Germany 385; United Kingdom 100; total EEC 385.
Metal, wrought, unwrought, and scrap.	69	67	West Germany 24; total EEC 27.
Uranium and thorium alloys	6	1	All to Italy.
Zinc:			
Ore and concentrate	24,100	7,282	Belgium-Luxembourg 4,501; Norway 2,703; total EEC 4,579.
Scrap	16	300	Italy 294; West Germany 6; total EEC 300.
Dust	1,578	1,185	Norway 1,175.
Slab	2,313	4,813	West Germany 4,080.
Semifabricated	2,549	2,600	West Germany 1,942; total EEC 1,980.
Other ores and concentrates	404	249	Sweden 22.
Other metals (germanium, hafnium, vanadium, uranium, zirconium, and gallium).	26	15	West Germany 9; Belgium-Luxembourg 3.
Nonmetals:			
Asbestos	11,390	10,062	Belgium-Luxembourg 3,067; West Germany 2,615; Argentina 1,471; total EEC 5,774.
Barite	22,226	18,351	Algeria 7,856; Nigeria 3,978; Switzerland 1,467; total EEC 1,415.
Borates	65	124	(2).
Cement—thousand tons	1,344	1,263	West Germany 269; Ivory Coast 141; Algeria 113; Madagascar 86; Switzerland 85; Italy 82.
Chalk	200,870	208,941	West Germany 89,157; Belgium-Luxembourg 53,213; Netherlands 24,814; total EEC 180,560.
Clays:			
Kaolin, including calcined	46,290	52,350	West Germany 40,873; Netherlands 3,368; Switzerland 1,698; Belgium-Luxembourg 1,128.
Refractory	292,001	306,014	Italy 164,830; West Germany 75,117; Belgium-Luxembourg 45,520; Switzerland 14,716.
Bentonite	2,613	2,867	Algeria 414; Belgium-Luxembourg 360; Tunisia 330; Switzerland 245.
Other	23,840	29,734	West Germany 20,537; Belgium-Luxembourg 5,990; Italy 1,518.
Crushed rock and gravel—thousand tons	1,566	2,123	Switzerland 942; West Germany 814; Belgium-Luxemburg 277; total EEC, 1,147.
Cryolite, natural	2	119	EEC 119.

TABLE 4.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962 [1]
Nonmetals—Continued			
Diamond, including powder. thousand dollars	887	1,294	West Germany 241; Belgium-Luxembourg 216; India 167; total EEC 565.
Diatomaceous earth	3,025	14,663	West Germany 11,713: Netherlands 1,075; total EEC 13,459.
Dolomite, including calcined	20,759	24,430	West Germany 7,678; Belgium-Luxembourg 4,776; Switzerland 2,596; Colombia 2,002; total EEC 12,650.
Earth pigments	5,431	6,261	Netherlands 1,769; West Germany 806; Morocco 400; total EEC 2,843.
Feldspar, leucite, and fluorspar	48,965	57,835	West Germany 34,648; Belgium-Luxembourg 10,352; Switzerland 3,238; total EEC 48,042.
Fertilizer raw materials:			
Animal and plant origin	23,034	28,645	Switzerland 16,327; West Germany 3,579; Spain 2,850; Canary Islands 2,640; total EEC 6,153.
Rock phosphate	3,565	1,228	Switzerland 939; total EEC 219.
Potash:			
Crude	244,745	139,875	Belgium-Luxembourg 68,334; Netherlands 48,447; West Germany 10,658; Switzerland 9,511; total EEC 130,080.
Potassium chloride. thousand tons	1,248	1,045	United Kingdom 227; United States 162; Japan 109; Ireland 61.
Potassium and magnesium sulfate.	10,998	13,503	Morocco 3,400; Switzerland 2,629; Tunisia 2,346; Italy 1,469.
Mixed	1,933	70,168	Belgium-Luxembourg 22,491; Switzerland 21,746; Italy 21,369.
Other	263	1,522	Switzerland 881; Italy 541.
Graphite	1,165	1,185	Belgium-Luxembourg 332; West Germany 328; Italy 173; United Kingdom 153; total EEC 833.
Gypsum and plaster	670,300	684,229	Belgium-Luxembourg 324,870; Sweden 134,352; United Kingdom 49,686; Netherlands 41,449; total EEC 395,821.
Lime	110,650	106,740	West Germany 68,516; Belgium Luxembourg 22,164; Algeria 4,703.
Limestone	247,199	223,995	West Germany 95,428; Belgium-Luxembourg 53,248; Switzerland 50,949; total EEC 148,696.
Magnesite	790	821	Gabon 661; Italy 79; total EEC 96.
Marble and other building stones	116,665	109,951	Belgium-Luxembourg 62,451; West Germany 24,785; Switzerland 12,819; total EEC 95,634.
Mica	164	164	West Germany 22; Spain 18.
Pumice and other natural abrasives	458	667	West Germany 559; total EEC 611.
Quartz and quartzite	1,781	1,448	Belgium-Luxembourg 779; Italy 504; total EEC 1,311.
Salt	98,097	104,748	Belgium-Luxembourg 78,719; West Germany 8,722; Netherlands 6,327; total EEC 93,769.
Sand thousand tons	999	1,061	Switzerland 419; West Germany 413; Belgium-Luxembourg 108; Italy 108; total EEC 629.
Slate	6,361	7,375	Netherlands 6,125; total EEC 7,290.
Soapstone and talc	44,257	44,819	West Germany 10,538; Switzerland 8,674; United Kingdom 7,119; Belgium-Luxembourg 5,016; total EEC 17,697.
Sulfur	574,975	547,042	United Kingdom 143,949; West Germany 73,854; Netherlands 55,582; Belgium-Luxembourg 32,313; total EEC 161,838.
Other mineral materials	169,230	206,502	Switzerland 175,336; West Germany 17,657; total EEC 27,353.
Slags and ashes:			
Other rejects of the iron and steel industry.	537,475	584,950	West Germany 400,150; Belgium-Luxembourg 106,496; Switzerland 60,002; total EEC 515,018.
Blast furnace dust	431,681	277,585	West Germany 167,648; Belgium-Luxembourg 109,937; total EEC 277,585.
Metalliferous ashes and residues	23,473	18,209	Belgium-Luxembourg 15,334; West Germany 1,399; Italy 892.
Other slags and ashes	92,244	34,846	Belgium-Luxembourg 16,705; Switzerland 12,826; West Germany 4,735; total EEC 22,020.
Thomas slag	287,955	299,318	Austria 139,218; Switzerland 119,857; United Kingdom 35,700.

TABLE 4.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962 [1]
Mineral fuels:			
Coal thousand tons	1,372	1,361	West Germany 674; Belgium 278; Spain 274; total EEC 1,027.
Coal briquets do	27	36	Italy 22; Switzerland 13; total EEC 23.
Coke do	106	160	West Germany 111; Italy 16; total EEC 129.
Petroleum refinery products:			
Gasoline thousand 42-gallon barrels	15,402	12,464	Algeria 3,424; United Kingdom 2,683; Switzerland 1,127; West Germany 778.
Kerosine do	5,244	4,766	Algeria 926; Singapore 552; Switzerland 523; Tunisia 435.
Diesel oil do	1,606	564	United Kingdom 307; Netherlands 80; Belgium-Luxembourg 77.
Gas oil do	16,294	18,099	Netherlands 3,495; Switzerland 2,845; Algeria 2,657; West Germany 2,518; United Kingdom 2,094.
Fuel oil do	18,647	15,347	United Kingdom 2,654; Algeria 2,071; Netherlands 1,403; Belgium-Luxembourg 749; Tunisia 692.
Lubricants do	1,276	1,306	United Kingdom 199; Algeria 195; Belgium-Luxembourg 173; Morocco 108.
Liquefied petroleum gas do	1,960	1,994	Algeria 538; Belgium-Luxembourg 390; Italy 238; Portugal 195.
Asphalt do	1,132	781	Algeria 377; Switzerland 184; Belgium-Luxembourg 105.
Other do	112	103	Morocco 44; Italy 21.
Total do	61,673	55,424	
Bunkers do	13,267	14,341	

[1] In the case of most items, the total export to the European Economic Community (EEC) is indicated; some part or all of this EEC total is duplicated in the listing of individual countries wherever Belgium, Italy, Luxembourg, the Netherlands, and/or West Germany appear as a separate entry.
[2] Data not available.
[3] Destinations given are those for steel commodities covered by the European Coal and Steel Community treaty; data on destinations for nontreaty items are not included.

TABLE 5.—Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962 [1]
Metals:			
Aluminum:			
Alumina, calcined	136,000	195,002	Guinea 146,965.
Bauxite	120,728	101,838	Greece 43,633; Guiana 32,047; Surinam 22,936.
Ingots	42,685	51,565	Cameroon 45,870.
Scrap	521	1,328	Algeria 442; Morocco 73; United Kingdom 41; West Germany 38; Canada 36.
Semifabricated	4,177	7,763	West Germany 3,328; Switzerland 769; Netherlands 609.
Antimony	980	2,175	Mainland China 876; U.S.S.R. 669; West Germany 414.
Bismuth	516	565	United Kingdom 300; Netherlands 105; Japan 74.
Cadmium	651	853	Belgium-Luxembourg 357; U.S.S.R. 154; Republic of the Congo 135; United States 91.
Chromite ore and concentrate	197,747	160,820	U.S.S.R. 55,537; Turkey 41,815; Madagascar 18,232; Iran 17,097.
Cobalt:			
Concentrate	9,309	9,695	Mainly from Morocco.
Metal	162	180	Belgium-Luxembourg 103; Republic of the Congo (Léopoldville) 30.

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962 [1]
Metals—Continued			
Copper:			
Scrap	6,630	9,035	Algeria 5,169; West Germany 1,439; total EEC 2,000.
Ingots, including alloys	11,507	7,055	Republic of the Congo (Léopoldville) 4,877; Belgium-Luxembourg 1,093; total EEC 1,385.
Refined	222,752	226,680	Belgium-Luxembourg 85,773; Federation of Rhodesia 35,570; Republic of the Congo (Léopoldville) 29,128; Canada 13,243; Chile 10,403; total EEC 91,667.
Semifabricated	4,791	6,192	West Germany 2,492; Belgium-Luxembourg 932; United Kingdom 571; total EEC 3,919.
Gold:			
Reexport troy ounces	120,212	69,381	Switzerland 35,752; United Kingdom 16,558; Netherlands 14,596.
All forms do	9,677	10,320	Switzerland 4,468; West Germany 1,736; Algeria 1,350; United States 1,250.
Iron and steel:			
Ore thousand tons	1,699	1,896	Sweden 612; Brazil 211; Peru 187; Belgium-Luxembourg 183; Morocco 173; Spain 159; total EEC 184.
Pyrite cinder	14,737	18,968	Italy 8,673; Spain 5,984; Belgium-Luxembourg 4,311; total EEC 12,984.
Scrap	742,380	367,102	Belgium-Luxembourg 174,888; West Germany 86,083; Netherlands 29,531; total EEC 291,587.
Pig iron, spiegel- eisen, and high carbon ferromanganese. thousand tons	189	175	West Germany 1,708; Belgium-Luxembourg 1,070; total EEC 2,893.[2]
Other ferroalloys do	23	15	
Ingots, blooms, and billets do	792	651	
Rolled steel do	2,344	2,617	
Cast iron pipes and other do	4	2	
Lead:			
Ores and concentrates	92,353	97,638	Morocco 68,512; Canada 12,781; Australia 5,005.
Scrap	3,083	2,351	Algeria 1,688; Belgium-Luxembourg 170; West Germany 153.
Pig	66,510	67,392	Belgium-Luxembourg 23,138; Morocco 20,849; Tunisia 13,706; total EEC 27,948.
Semifabricated	102	168	West Germany 93; Belgum-Luxembourg 17; United Kingdom 17; total EEC 119.
Magnesium:			
Scrap	5	21	Sweden 17.
Ingots	464	1,176	Canada 215; Norway 202; United Kingdom 141.
Wrought	52	48	West Germany 16; Austria 12.
Manganese ore and concentrate	701,391	717,285	Morocco 271,789; Republic of South Africa 230,922; U.S.S.R. 125,067; India 40,134.
Mercury 76-pound flasks	15,200	14,968	Italy 7,629; Spain 5,163.
Molybdenum:			
Ore	5,731	3,241	United States 2,776.
Metal	33	26	Austria 14; Netherlands 8.
Nickel:			
Matte	14,744	13,771	Mainly from New Caledonia.
Scrap	1,773	1,670	United Kingdom 432; West Germany 360; Switzerland 151.
Ingots	4,231	4,127	United Kingdom 2,926; Canada 1,085.
Anodes	316	371	United Kingdom 194; Switzerland 121.
Semifabricated	1,308	1,368	United Kingdom 704; West Germany 255; Switzerland 231.
Palladium group troy ounces	31,443	52,181	U.S.S.R. 24,595; Netherlands 23,181.
Platinum do	88,029	111,660	U.S.S.R. 61,922; United Kingdom 23,792 West Germany 9,581.
Silver:			
Crude thousand troy ounces	9,641	18,813	United Kingdom 10,921; West Germany 2,119; Belgium-Luxembourg 2,039; mainland China 1,927.
Semifabricated do	765	587	Switzerland 242; United Kingdom 183; West Germany 127.
Precious metal ashes and debris	4,632	24,994	Switzerland 19,189; Netherlands 2,022.
Thorium and uranium ores and concentrates.	1,569	3,226	Madagascar 1,024.

COMMODITY REVIEW

METALS

Iron and Ferroalloy Ores.—Although production of iron ore in France declined in 1963, the country maintained its position as the world's third largest iron ore producer, accounting for 11 percent of the world production and 73 percent of the European Economic Community (EEC) production. The bulk of the production continued to be from the Lorraine Basin. The minette ore from this basin, smelted to produce high-phosphorus basic pig iron, has met practically all the requirements of the steel industry of Eastern France and of the Saar area's steel industry of West Germany, as well as substantial proportions of the iron ore requirements of the Belgian and Luxembourg steel industries. The Ruhr steel plants of West Germany, however, continued to use very little minette ore. In 1963, French ore constituted 93 percent of iron ore shipments to French steel mills.

TABLE 6.—Marketable iron ore production by basin, total iron ore shipments and stocks

[2] Includes Belgium 8,165; West Germany 6,799 (of which 6,577 to the Saar); and United Kingdom 267.

Decline in production of iron ore in 1963 resulted partly from a 19-day strike. Increasing preference of the EEC steel producers for high-grade ore was also a factor. Although total imports of the Community in 1962 and 1963 were about 58 million tons annually, 21.4 million tons were imported from member countries (mainly France) in 1963, compared with 25.8 million tons in 1962. France also imported iron ore to meet part of the needs of the steel plants of the north and to supplement its own production of low-phosphorus high-grade iron ore for open-hearth and oxygen steel which has been produced in increasing quantities. These imports were nearly twice the 1962 level because the plant at Dunkirk used imported ore. The 2,766,000 tons imported in 1963 included 1,025,000 tons from Africa (Mauritania 339,000, Liberia 448,000 and North Africa 170,000); 503,000 tons from Sweden; 571,000 tons from Brazil; 361,000 tons from other non-EEC countries and 192,000 tons from EEC countries. To meet competition, price of Lorraine ore was reduced by US$0.25

Digitized by Google

per ton in July 1963. Prices in 1962 were about US$3.55 per ton on basis of 32 percent iron.

In 1962, approximately 76 iron mines were active in France of which 58 operated by 37 companies were in the Lorraine Basin. More than half of the mines in Lorraine each produced in excess of 1 million tons of ore in 1961, which was the last year for which output data by mines were available. Most of the mines are controlled by the large steel producers. Union Sidérurgique Lorraine (SIDELOR), with eight mines in the Lorraine Basin, produced 15 percent of the output and this company together with Lorraine-Escaut and de Wendel accounted for one-third of the basin's production.

TABLE 7.—Principal iron mining companies and mines

Mining company	Mines	1961 production (thousand metric tons)	Remarks
Lorraine Basin:			
Union Sidérurgique Lorraine (Sidelor).	Redange and Micheville-Brehan.	[1] 985	30 to 35 percent Fe worked open pit (Redange) and open pit and adit (Micheville).
	Landres-Mairy	[2] 1,638	Shaft entry.
	Orne-Pauline and Saint Marie.	[2] 2,254	32 percent Fe. Orne-Pauline is an adit mine; shaft entry to Saint Marie.
	Fond de la Nove	[2] 1,991	33 percent Fe; shaft entry.
	Aubone-Moineville	[2] 2,208	Shaft entry.
Total		9,076	
de Wendel et Compagnie.	Hayange, Moyeurre and Joeuf.	7,502	7,003,000 tons of the total was calcareous ore.
Société Anonyme de Lorraine-Escaut.	Angevillers, Tucquegnieux, Jarney and Longewy.	[2] 1,085 [1] 419	Calcareous ore 28 percent Fe; siliceous 32 percent; adit entry.
		[2] 1,381	35 percent Fe; shaft entry.
		[2] 870	34 percent Fe; shaft entry.
		[2] 134	Calcareous ore 27 percent Fe; siliceous.
		[1] 243	35 percent.
Total		4,132	
Société Minière des Tenes Renges.	Mont Rouge and Saint Michel.	[2] 1,980 [1] 1,088	Calcareous ore 28 percent Fe; siliceous 35 percent; adit entry.
Société Métallurgique de Knutange.	Aumetz	[2] 689 [1] 316	Calcareous ore 28 percent Fe; siliceous 37 percent; shaft entry.
	Boulange	[2] 503 [1] 441	Calcareous ore 28 percent Fe; siliceous 34 percent; shaft entry.
	Havange	[2] 479 [1] 313	Calcareous ore 30 percent Fe; siliceous 30 percent; shaft entry.
Total		2,741	
Société des Forges et Aciéries de Nord et Lorraine.	Hettange-Grande Ida	[2] 1,812 [2] 933 [1] 248	32 percent Fe; adit entry. Calcareous ore 30 percent Fe; siliceous 34 percent.
Total		2,993	
Union de Consommateurs de Produits Métallurgique et Industriels (UCPMI).	Sainte-Barbe	[2] 846 [1] 147	Calcareous ore 31 percent; siliceous 35 percent; shaft and adit entries.
	Roncourt	[2] 314 [1] 708	Are similar to that at Sainte Barbe; shaft entry.
Total		2,015

TABLE 7.—Principal iron mining companies and mines—Continued

Mining company	Mines	1961 production (thousand metric tons)	Remarks
Lorraine Basin—Continued			
Aciéries Réunies de Barbach-Eulch-Dedelange (ARBED).	Heydt, Kraemer, Burbach and Maxeville and Bois-du-Four.	[2] 1,423 [1] 578	Heydt is open pit; others are adit mines. Kraemer and Burbach produce calcareous ore 26 to 27 percent Fe, the other two mines siliceous ore, 28 percent Fe.
Total		2,001	
Société des Mines de Bazailles.	Bazailles	[1] 1,976	35 percent Fe; shaft entry.
Société des Mines d'Anderny-Chevillon	Anderng-Chevillon	[2] 1,795	33 percent Fe; shaft entry.
Société des Mines de Fer de Giraumont.	Giraumont-Fleury	[2] 1,766	32 percent Fe; shaft entry.
Société des Mines d'Ammermont-Dommary	Ammermont-Dommary	[2] 1,687	33 percent Fe; shaft entry.
Société des Forges et Aciéres du Nord et de l'Est.	Prennes	[2] 1,634	34 percent Fe; shaft entry.
Société anonyme des Hauts Fourneaux de la Chiers.	Saulnes-Sud and Gustav Wiesner.	1,595	Saulnes-Sud, siliceous ore, 36 percent Fe; open pit; Gustaf-Wiesner, calcareous ore, 28 percent, Fe shaft entry.
Société des Aciéreis et Tréfilleries de Neuve-Maisons, Chatillon.	Maron-Val-de-Fer	[2] 1,028 [1] 548	Calcareous and siliceous ores, 30 percent Fe; adit entry.
Total		1,576	
Other		16,845	Includes nine companies with production 1 to 1.5 million tons in 1961; 13 other companies with production 170,000 to 800,000 tons in 1961.
Normandy district:			
Société des Mines de Soumont.	Soumont	971	Siderite, some hematite, 46 percent Fe, after calcining.
Société des Hauts Fourneaux, Forges et Aciéries de Denain et Anzin.	La Fervière-aux-E'tangs	684	Carbonate ore, 47 percent Fe after calcining; shaft entry.
Compagnie des Forges de Chatillon, Commentry et Neuve-Maisons.	Halouze	585	Carbonate ore, calcined to 48 to 50 percent Fe; shaft entry.
Other		564	

[1] Siliceous.
[2] Calcareous.
[3] Siliceous and calcareous, undifferentiated.

Selective mining is required to assure a satisfactory blend of the calcareous and siliceous fractions. The average iron content dropped by 2.3 percent during 1953–62; in 1962 it was 28.8 percent on wet basis. On calcining, the grade is increased to about 39 percent iron; an additional 17 percent is combined oxygen. In the calcined ore, the ratio of iron to gangue is not much less than 1 : 6.[6]

As a result of mechanization, productivity in mines of Lorraine more than doubled during 1952–62. It averaged 13.5 tons per man-shift in 1962 for underground and open-pit mines combined, although in some mines it attained 24 tons per man-shift. Mining cost varied from US$1.50 to US$3.40 per ton, the lower figure being applicable only to open-pit mines.

Reserves of the Lorraine Basin were estimated at 3,300 million tons of calcareous ore and 2,800 million tons of siliceous ore.[7] Calcareous ore is defined as that having a $CaO:SiO_2$ ratio greater than 1.3:1. If the 1962 production ratio of calcareous ore to siliceous ore were to be continued, the reserves of the calcareous ore would be exhausted before all the siliceous ores would be used. Reserves of the two types of ores have a ratio of 1.2:1 in favor of the calcareous ore, but sale of the calcareous ore in 1962 was 3.9 times that of the siliceous ore. The Institut de Recherches de la Sidérurgie (IRSID) has done research on methods to increase the ratio of siliceous ore to calcareous ore in blast furnace burden and on methods to beneficiate the ore to meet competition from imported high-grade ores.

Beneficiation of minette ore has proven difficult because of a number of factors. Fine grinding is required to separate the different components of the ore, although with sintering this is not as serious a matter as it was prior to the initiation of sintering. Furthermore, in some cases, 25 to 40 percent of the ore's iron value is carried by chlorite in which the iron and silica are chemically combined. Also nearly 25 percent of total minette iron ore output consists of iron-bearing shales, which on grinding cause serious dust problems in the sinter plant.[8] Wet gravity separation followed by flotation has the disadvantage that the lime is removed easily and iron recovery is poor. Beneficiation involving previous drying of an ore which is not highly chloritic, followed by high-intensity magnetic separation, and preliminary roasting of chloritic ore followed by magnetic separation has been successful; therefore, building of a large plant is envisaged. Since 1950, quality of the ore fed to furnaces has been improved by sintering which has been widely adopted. Four new sintering plants were started during the year. It is expected that by 1965, 25 million tons of ore will be sintered annually and self-fluxing sinter in which limestone is added will be used increasingly.

Of the ferroalloy ores, France has produced only tungsten and insignificant quantities of manganese in the past. Manganese and chromite were the most important ferroalloy ores imported.

Total manganese consumption was 693,000 tons in 1962 (708,000 tons in 1961), of which the iron and steel industry consumed about 619,000 tons. The iron and steel industry also accounted for 80 to 90 percent of chromite consumption. The chemical industry was the principal consumer of the remainder of the chromite.

Iron and Steel.—*Production.*—In 1963, France produced 4.6 percent of the world's pig iron and 4.7 percent of the world's crude steel compared with 5.1 and 5 percent, respectively, in 1962. In spite of the relative decline, actual 1963 output of both pig crude steel increased. In the EEC, France ranked second after West Germany with 24 percent of the Community's crude steel output. Pig iron production in 1963 was equivalent to 81.4 percent of maximum possible output and crude steel production equalled 84.2 percent of capacity.

The number of operating blast furnaces has gradually decreased as a result of modernization programs which included the dismantling of numerous old and obsolete furnaces. The fourth plan for 1962–65

[7] Work cited in footnote 6.
[8] Work cited in footnote 6.

Digitized by Google

calls for renovating 26 old furnaces and building of 12 new ones to bring total capacity to 20.5 million tons by 1965, compared with 17.56 million tons in 1963.

In spite of a substantial reduction in rate of coke consumption in the blast furnace, France still had the second highest coke consump-

Digitized by Google

tion per ton of pig in the Community after Luxembourg, essentially because of the low grade of iron ore used. To reduce coke consumption further, liquid fuel and powdered coal injection as well as oxygen enrichment of the blast were practiced.

Thomas pig iron constituted 84 percent of the total output. The almost threefold increase in hematite and semihematite pig iron production, largely from imported ore, did not materially alter the predominant position of Thomas pig iron.

TABLE 9.—Estimates of effective production capacity of pig iron and crude steel

(Thousand metric tons)

	1959	1961	1962	1963	1965
Pig iron	13,500	15,650	16,100	17,560	20,500
Crude steel	16,180	18,560	19,545	20,835	[1] 22,400

[1] The fourth plan's target of 24.5 million tons output in 1965 has been revised downward.

TABLE 10.—Iron and steel production by processes

(Thousand metric tons)

	1959	1960	1961	1962	1963
Pig iron:					
Thomas	10,937	12,337	12,672	12,169	12,069

Electric	1,291	1,494	1,566	1,526	1,526
Bessemer	109	102	112	101	81
Kaldo, L-D, and similar	----	95	423	658	1,341
Creuset	2	2	3	3	2
Total	15,219	17,281	17,570	17,240	17,557

[1] Includes 9,448 tons of special pig iron for steelmaking.

Practically all the Thomas pig iron was produced in the east and north districts; the respective share of these districts in total output in 1963 were 74 and 19 percent, respectively. Foundry iron was produced mostly in the center and southeast districts. Of the 97 blast furnaces in operation on December 31, 1963, 72 were in the east, 15 in the north, 5 in the southwest, 1 in the southeast and 4 in the west districts.

Thomas steel and open-hearth steel constituted respectively 56 percent and 27 percent of 1963 total crude steel output. There has been a significant increase in steel produced by the Linz-Donawitz, Kaldo, and similar processes, using oxygen, although tonnagewise the output is still small.

Production of high-grade and alloy steel amounted to 1,132,000 tons in 1963, compared with 1,459,000 tons in 1962 and 1,532,100 tons in 1961. Of the 1963 total, structural high-grade carbon steel represented

Digitized by Google

36.7 percent, structural alloy steel 37.8 percent, ball-bearing steel 5.2 percent, and stainless steel 14.8 percent. Stainless steel production increased to 212,000 tons in 1963 from 179,000 tons in 1962.

As with pig iron, the east and north districts were predominant in steel; those districts accounted for 64.4 and 25 percent, respectively, of the total production in 1963. In the same year, 82.8 percent of the Thomas steel was produced in the east district. The east and north districts each produced 46 and 44 percent of the open-hearth steel, respectively. Fifty-eight percent of the electric steel originated in the center and southeast districts.

[1] Detail does not add total because of rounding.

Source: Bulletin de la Chambre Syndicale de la Sidérurgie Française.

In rolled steel, the share of flat products in total output continued to increase; growth in this category consisted mainly of cold rolled thin sheets. Investment in flat product facilities accounted for 53.4 percent and 60 percent, respectively, of total investment expenditures in rolling mills in 1961 and 1962. Of the total tinplate production in 1962, 421,400 tons was made electrolytically and 172,400 tons was made by hot dip.

Investments in the iron and steel industry as a whole during 1961 and 1962 were equivalent to US$395 million and US$435 million, respectively. Investment in 1963 dropped 25 percent to about US$326 million. Keen competition for the steel market and resulting low prices adversely affected resources for self-financing of the industry. Furthermore, the industry's indebtedness now corresponds to 70 percent of yearly sales. Production of steel pipes increased slightly.

Consumption.—Apparent consumption of steel [9] converted to crude steel totaled 16,107,000 tons compared with 15,386,000 tons in 1962 and

[9] In the trade data used for calculation of apparent consumption only European Coal and Steel Community (ECSC) treaty items have been included which comprise the majority of rolled products but exclude forged products, cold drawn wire and steel pipes and fittings.

Digitized by Google

14,718,000 tons in 1961. Per capita consumption for 1961, 1962, and 1963 were 337, 329, and 320 kilograms, respectively. Delivery of domestic steel to the home market in 1963 remained practically the same as in 1962 although there was a 4-percent consumption increase.

[1] For making pipes and tubes, wire drawing, cold rolling, etc.
[2] Total excludes pipes, cold drawn wire, and forgings.

Rate of activity of the consumer goods industries followed an upward trend; notably automobile manufacture increased by 13 percent. Steel consumers met the increased demand by drawing on their stocks and through increased imports. Consumer stocks were low at the end of the year.

The increase in the industrial production in 1962 (6 percent) was not paralleled by similar increase in steel demand. This is explained by the fact that the index of production refers to a number of industries which consume little or no steel. Furthermore, capital goods industries expanded at a slower rate than in the previous year. A similar disparity between the activity of steel-using industries and steel deliveries from French mills is explained by increased imports and withdrawal from stocks.

International steel prices continued to decline for the 4th consecutive year until the latter months of 1964 because of competition from other sources. The average value of French steel exports to countries outside the ECSC dropped from US$153 per ton in 1960 to US$126 in 1962 and US$116 in 1963. This situation led to mounting pressure to increase the external tariff of ECSC countries for rolled steel products.

Trade.—In 1963, France exported 292,000 tons of pig iron and blast furnace ferroalloys, 268,000 tons ingots, blooms, and billets as well as 4,803,000 tons of rolled steel including steel pipes, cold drawn wire, and forged products.[10] Of the rolled steel products, approximately 140,000 tons were special and alloy steels. In addition 122,000 tons of cast iron pipes and accessories were also exported. The European Economic Community received 88 percent of the pig iron, 51 percent of ingots, blooms, and billets as well as 54 percent of ECSC treaty rolled steel items (which exclude steel pipes and fittings, cold drawn

[10] Office Statistique des Communautés Européenes Sidérurgie. 1964, No. 2.

Digitized by Google

wire, and forged steel). Other large destinations for steel and the quantities shipped to them were Switzerland—315,300 tons; United Kingdom—114,000 tons; other European countries—630,000 tons; United States—271,100 tons; Asia and Oceania (excluding franc zone countires)—264,700 tons; Africa (excluding franc zone countries)—80,000 tons; and total franc zone—376,900 tons.

Imports of steel into France increased significantly. The EEC was the import source for 81 percent of pig iron and blast furnace ferroalloys, 95 percent of ingots, blooms, and billets, as well as 92 percent of rolled steel. Sheets, including tinplate constituted the largest commodity group both in imports and exports.

Source: Office Statistique des Communautés Européennes. Sidérurgie, 1964, No. 2. Data are preliminary figures and are not exactly reconcilable with those given in table 14.

The opening of the Moselle Canal between Thionville in Lorraine and the junction of the Moselle and Rhine Rivers at Koblenz in West Germany promised to improve the competitive position of the Lorraine steel industry. The industry expected to make savings in the transport costs for imports of Ruhr coke and exports of steel to West Germany, particularly in the growing steel market of southern Germany. The 271-kilometer canal can handle 1,500-ton vessels.

Principal Companies and Plants.—There were 55 firms with 76 plants producing iron and steel in France during 1963. Of these, six firms produced 69 percent of 1963 total crude steel output. In terms of annual production capacity, 60 of the 75 plants had the following size distribution: More than 2 million tons—1; 1.5 to 2 million tons—2; more than 1 to 1.5 million tons—4; more than one-half to 1 million tons—9; half a million tons and less—45.

The integrated plant at Dunkirk, which started production of pig iron in February 1963, was the largest and newest plant in France. It has two blast furnaces, designed to produce 5,000 tons of pig iron per day, and three 140-ton converters. Plates and hot rolled strips and coils are main products. The plant operated largely on imported high-grade iron ore. De Wendel and SIDELOR announced their intention to establish a 1.6-million-ton-per-year-capacity plant at Gandrange on the banks of the Moselle Canal. It will consist of an oxygen steel plant and a continuous merchant mill.

TABLE 16.—Selected iron and steel companies

District and company	1963 production (thousand metric tons)	Plant location	Furnaces				Remarks
			Blast	Thomas converter	Open hearth [2]	Oxygen converter	
East: [1]							
Union Sidérurgique Lorraine (Sidelor).	2,400	Aubone, Hautmont, Homécourt, Micheville and Rombas.	21	17	9 (3)	----------	The company was formed in 1950 when certain Lorraine Basin operations of Pont-à-Mousson and Marine et Homécourt were joined. The company produces heavy sections, wire rods, merchant steel, and strip.
Société Lorraine de Laminage Continue S.A. (SOLLAC).	(3)	Ébange, Sérémange, Florange.	------	4	4	----------	Formed in 1948, it began operations in 1953. De Wendel has controlling interest, Pont-à-Mousson owns 40 percent, and three other companies own the small remainder of the shares. Sollac has only rolling mills. It produces sheets and strips and owns a large part of France's electrolytic tin capacity.
Société des Fonderies de Pont-à-Mousson.	(3)	Pont-à-Mousson, Belleville.	5	4	--------	----------	Company produces heavy plate, forgings, centrifugal cast pipes and tubes.
Lorraine-Escaut	2,056	Brevilly, Thionville, Longwy, Sedan, Anzin, Maubeuge, Laval Dieu.	14	17	16(8)	----------	Owned 49 percent by De Wendel and 51 percent by Longwy-Raty. Produces heavy sections, wire rods, merchant steel, sheets, and strips.
De Wendel et Cie S.A.	2,736	Hayange, Moyeuvre, Joeuf, Messempre.	24	17	6	----------	Produces heavy sections, wire bars, merchant steel, sheets, and strips.
S.A. des Hauts Fournaux de La Chiers.	(3)	Longwy, Blagny, Vireux-Molhain.	5	5	5(2)	----------	Produces wire bars, merchant steel, sheets, and strips.
Société Métallurgique de Knutange.	1,600	----------	9	6	--------	----------	Produces heavy sections, merchant steel.
S.A. des Laminoirs Hauts Fourneaux, Forges, Fonderies et Usines de la Providence.	(3)	Rehon, Hautmont.	6	5	3(1)	----------	Produces sections, merchant steel sheets and strips.

See footnotes at end of table.

TABLE 16.—Selected iron and steel companies—Continued

District and company	1963 production (thousand metric tons)	Plant location	Furnaces				Remarks
			Blast	Thomas converter	Open hearth [2]	Oxygen converter	
East [1]—Continued							
Union de Consommateurs de Produits Métallurgiques et Industriels (UCPMI).	(3)	Hagondange	6	5	4	2	Produces heavy sections and wire bars.
North:							
Union Sidérurgique du Nord de la France (USINOR).	3,297	Dunkirk, Denain, Montataire, Valenciennes, Louvroil-Hautmont, Anzin.	14	12(1)	20	30 L-D and 1 oxygen.	Formed in 1948 by merger of Denain-Anzin and Forges et Acieries du Nord et d'Est, it is largest steel company. Produces heavy sections, plates, merchant steel, sheets, and strips.
Société Metallurgique de Normandie.	(3)	Mondeville	3	4	4		Produces merchant steel, sections, wire rods, drawn wire products, rounds for tubes.
Center:							
Cie des Ateliers et Forges de la Loire (CAFL).	(3)	Onzion, St. Etienne, St. Chamond, Ondaine, Le Boucau, Firminy, Unieux, Assailly.	4	------	5(11)	------	Produces wire bars, merchant steel, strips, and sheets (more than 3 millimeters thickness).
Société des Forges et Ateliers de Creusot (USINES Schneider).	(3)	Le Creusot	------	------	2(6)	------	Produces heavy and medium plates and sheets in special and alloy steels, wire rods, round and square.

[1] Districts apply to majority of plants owned by each company.
[2] Number in parentheses refers to electric furnaces
[3] Data not available.

Application of the Société Métallurgique de Knutange, Paris, and l'Union de Consommateurs de Produits Métallurgiques et Industriels (UCPMI), Paris, to merge was under study by the High Authority of the ECSC at yearend. The proposed new firm, to be called La Société Mosellane de Sidérurgie (SOMOSID) with a capital of Fr150 million, would rank as France's fifth largest steel producer. Its 2 plants at Hagondange and Knutange in Lorraine have a coke oven plant, 14 blast furnaces, 2 Thomas converters, and 1 open-hearth furnace as well as rolling mills and metalworking installations. The two firms in 1962 produced 4.8 million tons of iron ore, 5.6 million tons of pig iron, and 1.6 million tons of steel.

Ferroalloys.—France's diversified ferroalloy industry continued to produce a wide variety of ferroalloys and ferroalloy metals in blast furnaces, electric furnaces, and by alumina-thermic methods. Output was mainly for domestic consumption. The large steel companies in the north and east produced special steels and much of the blast fur-

Digitized by Google

nace ferroalloys. The Société des Acièrs fin de l'Est and Société des Acièries de Pompey among others also produced special steels in the east. However, electrometallurgical plants for production of these steels and ferroalloys were concentrated in the center and southeast districts, with the St. Étienne-Lyon area as the most important center. Hydroelectric power plants in southeast France have consistently supplied low-cost electricity to the electrometallurgical plants. Major producing firms in 1963 were Compagnie des Ateliérs et Forges de la Loire with plant at St. Étienne, Société des Forges et Ateliérs du Creusot with plant at Le Creusot, Société d'Électro-Chimie, d'Électro-Métallurgie et des Acièries d'Électriques de Ugine (Ugine) with plant at Ugine, and Compagnie de Produits Chimiques et Electrométallurgiques Péchiney (Péchiney), with plant at Chedde. Ugine, the largest ferroalloy producer in the country, continued to make cobalt, manganese, molybdenum, titanium, vanadium, and zirconium metals as well as their ferroalloys. Péchiney produced chromium and manganese metals at its Chedde plant and ferrochrome at Isbergues in Pas-de-Calais Département.

TABLE 17.—Consumption of ferroalloy metals and production of electric furnace ferroalloys by the iron and steel industry

(Metric tons)

Commodity	1960	1961	1962	1963
Consumption of ferroalloy metals:

[1] Adjusted to 50 percent silicon. Includes minor ferro-silico-magnesium, ferro-silico-aluminum, and ferro-silico-manganese-aluminum alloys.
[2] Data not available.
[3] Contained ferroalloy metal.

Source: For consumption data—Syndicat des Producteurs d'Aciers fins et spèciaux. For production data—Ministère de l'Industrie, Bureau Centrale de Statistique Industrielle (Paris). Annuaire de Statistique Industrielle. Seizième Année, 1963, p. 59.

Of the ferroalloys produced in electric furnaces in 1962, nearly 50 percent was ferrosilicon which was produced from domestic quartz and quartz-bearing rocks. Manganese ore as well as blast furnace ferromanganese and spiegeleisen serve as raw material for electric-furnace production of medium and low carbon ferromanganese. Since

Digitized by Google

1959, ferronickel production has not been reported; the ferroalloy was imported from the plant of Société le Nickel in New Caledonia. Electrolytic nickel was made by Société Sopumet.

France exports ferromanganese regularly. A substantial share of the chromium metal output is also exported—55 percent in 1962, mainly to the United States.

Iron and Steel Scrap.—Scrap collection increased by 1.7 percent. Consumption of scrap per unit production of pig iron and crude steel diminished so that total consumption of the steel industry was only 0.3 percent more than in 1962. Sources of scrap supply in the last 3 years were as follows:

	1961	1962	1963
Home scrap (steel industry's own):			
Thousand tons	4,070	4,041	4,103
Percent of all scrap	54.1	57.6	58.3
Purchase:			
Thousand tons	3,455	2,974	2,934
Kilograms per ton of steel produced	200	175	170

Nonferrous Metals.—France was more important as a consumer of nonferrous metals than as a producer or refiner. Of the major commodities in this group, only aluminum was produced in significant quantities from domestic resources. Most of the copper, lead, and zinc requirements were met by imports in form of concentrates and metals. Antimony, bismuth, cadmium, chromium, cobalt, magnesium, manganese, gold and silver, thorium and uranium metals were produced directly or as byproducts from domestic and imported ores.

Société Minière et Métallurgique de Penarroya (Penarroya), Société Anonyme des Mines et Fonderies de Zinc de la Vieille Montagne, and Compagnie Royale Asturiénne des Mines were the principal firms producing lead, zinc, and their byproducts, and Compagnie des Produits Chimiques et Electrométallurgiques. Péchiney (Péchiney) was dominant in aluminum production.

In addition to principal primary nonferrous metallurgical plants tabulated, there are secondary producers of nonferrous metals. Their products include aluminum, copper, lead, zinc, and tin.

758-002—65——30

TABLE 18.—Principal primary nonferrous metal plants

Name and location	Type of plant	Annual capacity (tons)	Remarks
Aluminum:			
Compagnie de Produits Chimiques et Électro-Métallurgiques Péchiney:			Capital of Péchiney in 1962 was Fr430 million ($71 million). In 1962 it produced 472,000 tons of alumina and 239,100 tons of aluminum.
Gardanne	Alumina	365,000	Bayer process; further expansion is planned.
Salindres	do	200,000	
St. Auban	do	40,000	
Noguères	Aluminum	90,000	New plant completed in 1960 is to be enlarged to 120,000-ton capacity. Power is obtained from a thermal plant using Lacq natural gas.
St. Jean-de-Maurienne	do	69,000	Aluminum alloys are also produced.
Sabart	do	18,900	
Auzat	do	18,500	
L'Agentière	do	17,500	
Chedde, Pa Praz, Riouperoux, and La Saussaz.	do	32,700	
Ugine:			
La Barasse	Alumina	150,000	
Lannemézan	Aluminum	50,000	Much of the required power for expansion will be from thermal plant using natural gas.
Venthon	do	16,500	
Société Francaise pour l'Industrie de l'Aluminium: Marseille.	Alumina	60,000	
Copper:			
Compagnie Générale d'Électrolyse du Palais: Palais-sur-Vienne.	Copper smelter, electrolytic and copper refining facilities (electrolytic refinery).	26,500	Produces copper cathodes, wire bars, billets and slabs and by-product nickel sulfate; 1961 production 22,854 tons copper.
Lead:			
Société Minière et Métallurgique de Penarroya: Noyelles-Godault.	Dwight-Lloyd roasters, water jacket lead smelters and refining facilities, pipe and rolling mill.	80,000	Soft and antimonial lead are produced and semifabricated; silver and bismuth are also recovered; 1961 production: lead 71,609 tons; silver 77,114 kilograms.
Nickel:			
Société Le Nickel S.A.: Le Havre.	Nickel refinery		Produces nickel metal and oxide.
Zinc:			
Société Miniere et Métallurgique de Penarroya: Noyelles-Godault.	Zinc smelter and rolling mill.	20,000	Zinc blast furnace using the Avonmoth process. Slab and semifabricated zinc are produced; 1961 production 16,200 tons of slab zinc.
Compagnie Austurienne des Auby-lez-Douai (Nord).	Zinc smelter, refinery, rolling mill; cadmium recovery plant.	60,000	Plant uses two New Jersey zinc distillation units. Sulfuric acid is also produced using blende roaster gases.
Mortagne-du-Nord	Zinc smelter	10,000	Closed in 1962.
Société des Mines et Fonderies de Zinc de la Vieille Montagne:			
Viviez (Aveyron)	Electrolytic zinc, rolling mill.	78,000	Plant also makes zinc base alloys and zinc sulfate and recovers cadmium; 1961 production 67,600 tons zinc.
Creil (Oise)	Zinc smelter	10,000	New Jersey distillation plant. Zinc white is also made.

In 1963, the value of imports of all nonferrous metals and semimanufactures, ores, and scrap totaled US$377 million compared with US$365 million in 1962. Precious metal imports, other than gold, added another US$43 million to the total. Of the 1963 imports of nonferrous metals, semimanufactures and scrap copper accounted for

Digitized by Google

US$165 million followed by lead (US$16 million), zinc (US$23 million), nickel (US$16 million), aluminum (US$41 million) and tin (US$30 million). Some of the important sources of imports were Belgium-Luxembourg, Federation of Rhodesia and Nyasaland, Republic of the Congo (Léopoldville), and the United States for copper; the United Kingdom for nickel; Cameroon for aluminum; Belgium-Luxembourg, Morocco, and Tunisia for lead; and Belgium-Luxembourg for zinc.

French exports of nonferrous base metals were valued at nearly US$175 million in 1963. Significant commodities included aluminum and copper as metal and semimanufactures, as well as ingot nickel. Main recipients of these exports were the Common Market countries for aluminum, copper, lead and zinc and the U.S.S.R. for nickel.

Bauxite and Alumina.—In 1963, France produced 6.6 percent of world bauxite and ranked fifth among world producers. Domestic production provided an adequate supply for the aluminum industry and for export of 205,900 tons. Visible and indicated reserves were estimated to total 30 million tons in 1962 of which 80 percent was in the Département of Var and the remainder in Hérault and Ariège in the south of France. The inferred reserve was estimated at 40 million tons. Usable reserves have increased because the aluminum industry in 1962 successfully used bauxite with 7 percent silica. Of the 1962 output, 1,766,000 or 82 percent was produced in Var and 392,000 in Hérault and Ariège.

Bauxite was mined by subsidiaries of Péchiney and by the following companies (1961 production in parentheses): Bauxites et Alumines de Provence 336,000 tons; Ugine 199,000 tons; Comptoir de l'Extraction et de Vente de Bauxites 148,000 tons; Bauxites de France (unreported); and Union des Bauxites (unreported). Péchiney operated five mines (Le Récoux, Maron, Pélicon, Engardin, Mazauges) in the Var Département centered around the town of Brignoles, three in Hérault (Arboussas, Camebelliès and Cazouls-les-Béziers) and one in Ariège (Péreille). The Récoux-Maron area at the north end of the region traditionally has supplied a large part of the bauxite for alumina production. Nearly three-fourths of the 1962 production was from underground mines. Operations in Hérault are open pit.

Of the total calcined alumina produced in 1962, 589,000 tons was used in aluminum production. In addition to domestic alumina production, Péchiney and Ugine through their participation in Compagnie Internationale pour la Production de l'Alumine (FRIA) obtained alumina produced in Guinea. Export of alumina to Poland and larger exports to Spain were instrumental in increasing 1962 alumina exports.

Aluminum.—After increasing primary aluminum capacity from 159,000 tons in 1955 to 312,000 tons in 1962, the industry had a pause in expansion during 1963 and was concerned with fuller utilization of existing capacity, lowering power consumption, and improving efficiency of the industry. With production constituting 27.5 percent of the West European production in 1963, France was the fourth largest aluminum producer in the world. The Government's fourth plan calls for aluminum production of 345,000 tons by 1965. Expan-

Digitized by Google

sion in production reportedly will be based on thermal power produced from natural gas.

Production of semimanufactures and castings increased by 52 and 25 percent, respectively, during 1959–63. Of aluminum castings produced in 1963, 18,800 tons were die castings.

France's consumption of aluminum for domestic use and exports increased to 242,500 tons in 1963 compared with 235,600 tons in 1962 and 152,000 tons in 1957. Consumption between 1957 and 1963 rose at an average annual rate of about 10 percent. Part of the growth resulted from increases in French exports of semifabricated aluminum. End-uses of aluminum by percentage, were probably about the same as in 1962: Transportation 33; construction 8; electrical 13; packaging 12; mechanical equipment 9; domestic and office equipment 10; powder and granules 3; chemical and agricultural 3; iron and metallurgical 3; other 7.

Exports of aluminum ingots (alloyed and nonalloyed) totaled 124,691 tons (17.5 percent more than in 1962) and of aluminum semimanufactures, including foil, 33,079 tons. Imports (excluding alloys) from all sources other than Cameroon were 7,213 tons and from Cameroon 45,535 tons. Imports of alloys and semimanufactures including foils were 3,123 tons and 12,181 tons, respectively.

Since July 1963, crude aluminum imports (nonalloyed) from Common Market countries have been subject to an 8 percent duty whereas aluminum has been subject to a 9-percent common external tariff. The import tariff from non-Community countries was 13.4 percent. For semimanufactures, the two sets of tariffs are very close and vary from 15 to 22 percent, depending on the type of semimanufacture.

All aluminum sales in France were handled by L'Aluminium Français, a holding company in which several companies making aluminum and aluminum products participate. In addition to aluminum produced in France, L'Aluminium Français disposed of a certain share of aluminum produced by Compagnie Camerounais de l'Aluminium Péchiney-Ugine (ALUCAM) in Edea, Cameroon. This share amounted to 46,400 tons in 1962 and 47,033 tons in 1963, so that total aluminum available to France in 1963 was 345,398 tons compared with 340,910 in 1962. Total shipment by L'Aluminium Français was 336,500 tons in 1962 compared with 321,000 tons in the previous year.

In 1963, Péchiney and Ugine remained France's only primary aluminum producers. Péchiney, with 10 reduction plants, produced about 234,700 tons of aluminum in 1963 (78.6 percent of total production) and Ugine produced 63,700 tons. The last phase of expansion of Ugine's Lannémezan plant was completed at the beginning of the year and the plant was producing at a rate 20 percent higher than in 1962. Péchiney and Ugine held joint interests in other aluminum companies and cooperated in foreign operations; and, through l'Aluminium Français, they cooperated in power and raw materials distribution, research, and the development of markets.

Aluminum reduction plants were mainly in the Alps and Pyrénées areas where hydroelectric power was available. However, Péchiney's Noguères plant, the largest and most modern plant in France, and the new Lannémezan plant use thermal power generated from the Lacq gasfield.

Digitized by Google

Nearly half of the 40 to 50 aluminum rolling mills and fabrication plants of France are located in or near Paris. Compagnie Générale du Duraluminium et du Cuivre (Cégédur) is Péchiney's subsidiary in aluminum fabrication. Cégédur's largest plant, at Iasoire, had an annual capacity of 70,000 tons of rolled and extruded products. Tréfileries et Laminoirs du Havre and Compagnie Française des Métaux, the other principal producers of aluminum products, merged in 1962 into a single company called Tréfimétaux which was reported to be the largest producer of aluminum and copper mill products in the EEC. The largest plant of Tréfimétaux was in Paris and had a capacity for production of 40,000 tons of sheet, plate, extruded wire, and cable. Ugine does not have rolling mills of its own, but through an 8-percent ownership of Cégédur and participation in l'Aluminium Français, avails itself of rolling facilities.

Also during 1962, a consortium consisting of Cégédur, Tréfimétaux, and Forges de Crans created a new company called Rhenalu, which planned to construct a large aluminum rolling mill at Neuf-Brisach-Biesham, in eastern France. When this mill is completed in 1965, it will be one of the largest mills in Europe, with an annual capacity in excess of 100,000 tons.

Aluminium Français has two research laboratories at Chambery, Savoie, and at Centre Technique de l'Aluminium, Paris.

Copper.—The few hundred tons of mine production of copper were obtained from gold-silver-arsenic ores of the Salsigne mine at La Combe but the metal was not recovered in France. France did not have facilities for smelting copper ore, and the copper smelting (secondary) and refining industry was relatively small. Despite the small production the country was the sixth world consumer of copper in 1962 and regularly exports significant quantities of copper-base semimanufactures. Requirements were met by imports of refined metal. These imports in 1963 totaled 220,600 tons unwrought and 10,737 tons wrought. Refined copper was bought under long-term arrangements by the Groupement d'Importation et Répartition des Métaux, a private but Government-approved organization for importation and distribution of copper at a uniform price.

Consumption of primary and secondary copper in 1963 was 249,300 tons compared with 243,700 in 1962. Production of semifabricated copper totaled 359,600 tons, indicating direct use of a large tonnage of scrap—113,200 tons metal content in 1962.[11] Total scrap consumption in 1963 was 153,600 tons including scrap used for production of secondary copper. Because much of this scrap was generated locally, imports of copper scrap were relatively small, less than 10,000 tons in 1962 and reportedly 8,500 tons in 1963. Gross weight of shipments of copper and copper alloy semimanufactures (exclusive of copper castings and copper sulfate) in 1963 totaled 355,846 tons[12] which included 159,626 tons of wire, 97,300 tons of rods and sections, 60,994 tons of sheets and strips, and 37,927 tons of tubes.

Shares of principal consumers of copper in 1962 in percent were as follows: Electrical industry, including machinery production and

[11] Metallgesellschaft Aktiengesellschaft. Metal Statistics, 1954–63. Frankfurt am Main (Germany), 1964, pp. 131–134.
[12] Work cited in footnote 11.

Digitized by Google

power distribution 51; building, public works, merchant marine and aircraft 17; export of semimanufactures 9; road vehicles 7; post, telephone, and telegraph 4; and miscellaneous 12.

Compagnie Générale d'Électolyse du Palais has accounted for nearly all the electrolytic copper output. Several companies, including Palais, produced secondary copper, as well as brass, bronze, and other alloys from scrap. Among these were J. Barthelemy and V. Champigneulle at Nancy; Compagnie Française des Métaux at Givet; Société Française des Métaux at Alliage Blancs at St. Denis and Lyon; Société Anonyme Affineries de Juvisy at Juvisy; Société Française d'Affinage de Cuivre at Poissy; and Péchiney's Affinerie de la Corneuve which produced brass and bronze ingots.

Prices of copper during the last 6 months of the year varied from $648 to $656 per ton.

Lead-Zinc.—In 1962, there were 10 lead-zinc mines in production. Three of these (Pessens, l'Hermita, and Villenauvette), operated by Société des Couleurs Zinciques, produced zinc only for making zinc white and lithopone. Vieille Montagne had one active mine in southern France called Gard at Saint Félix de Pallières. Penarroya operated six mines also in southern France: Les Malines, Peyrebrune, Pierrefitte, La Plagne, St. Sebâstien-d'Aigrefeuille, and Loubatière; the last two mentioned were closed in 1962 after producing a total of 8,982 tons of lead minerals. Penarroya was developing the new Largentièra lead mine in 1963, and this property was to start production in 1964. A new zinc mine was put in operation at Figeac during 1963; information on its ownership is not available. Most of the lead ores, particularly from Plagne, are argentiferous. Ores from Pierrefitte, Malines, and Peyrebrune have more zinc than lead.

Penarroya remained the largest producer of lead-zinc ore in France and the sole producer of primary lead. In 1962 the company produced 18,767 tons of lead and 22,085 tons of zinc concentrates in France. Its metal production was 75,569 tons of lead and 21,076 tons of zinc.

Vieille Montagne and Compagnie Asturienne des Mines were the principal zinc producers, mainly operating on imported ore. Production of Vieille Montagne in France in 1961 was 75,942 tons of zinc and 1,353 tons of zinc dust.

Penarroya produced all primary lead in one plant at Noyelle-Godault. The Avonmouth-type smelter for treating mixed lead-zinc ores in this plant, which began operation in May 1962, attained full capacity during the year. The bulk of the lead, however, was produced in a blast furnace. Three companies produced secondary lead from scrap in four plants. Secondary and antimonial lead constituted about one-fifth of the total lead output of France.

Consumption of lead in 1963 totaled 170,100 tons (156,300 tons in 1962); thus domestic primary and secondary smelter production (including metal recovered from imported ores) was equal to about two-thirds of consumption. In 1962, the lead content of domestic ore output provided only 14 percent of the domestic smelter production and met only 9 percent of domestic requirements. End-uses of lead in 1962 and their percent of total consumption were: Cable shielding 31, semimanufactures 16, batteries 24, oxides 16, and other 13.

Digitized by Google

Although the industry supposedly experienced difficulty in obtaining adequate supply of ores and concentrates, imports in 1963 totaled 132,270 tons, 35 percent more than in 1962. Imports of lead metal, including alloys, were 67,789 tons, and those of wrought lead were 239 tons. The bulk of ore imports comes from Morocco where Penarroya, through Penarroya-Moroc, participates in three mining companies and the smelter of Fonderies Penarroya-Zellidja.

Lead prices in dollars per ton during the year were as follows: December 31, 1962, to April 17, 1963, US$170; April 18 to May 28, 1963, US$178; May 29 to August 12, 1963, US$186; August 13 to August 21, 1963, US$190; and August 22 to yearend, US$194.

Although the Mortagne zinc smelter of Asturienne des Mines stopped working in 1962, there was a slight increase in zinc production resulting from the operation of the Avonmouth-type smelter at Noyelle-Godault. This furnace produced 16,683 tons of zinc and 1,851 tons of lead in 1962. With operation of this plant, horizontal retorts for zinc production were shut down. Semimanufactures production totaled 64,900 tons, of which 62,100 tons were rolled zinc. A larger share of French zinc consumption was produced in French installations than was the case with lead, although the share of domestic ores in total output was quite small (8.7 percent in 1962).

Zinc consumption in 1963 was estimated at 180,800 tons, evclusive of 6,800 tons of zinc dust. Galvanizing accounted for 71,000 tons of the total. In 1962 relative shares of various end users in percent were as follows: Rolled zinc 38; galvanizing 31; zinc alloys 13; brass 11; zinc oxide 5; miscellaneous 2.

In view of smaller domestic ore production, the industry had difficulty in fully meeting ore requirements of the smelting industry. In 1963, imports of zinc ore and concentrate totaled 281,000 tons, zinc ingot metal (including alloys) imports were 20,625 tons, and those of wrought zinc were 2,556 tons.

Capacity for roasting zinc ores in France was sufficient to meet the requirement of the smelters; however, some of the domestic and North African ore used in France was roasted abroad, particularly in Belgium.

Prices of zinc increased during the year from US$207 per ton during the January-March 15 period to US$263 from September 12 to yearend.

Nickel.—Société le Nickel produced nickel and nickel oxide from matte imported from New Caledonia in the company's only plant in France which is at Le Havre. Some secondary nickel also was produced by electrolysis of monel metal and scraps of copper-nickel-zinc alloys; 431 tons of secondary nickel were produced in 1962.

In 1963, 1,846 tons of nickel and 4,459 tons of nickel alloy semimanufactures were produced. The nickel alloys were principally copper-nickel and copper-nickel-zinc alloys. Decline in production of nickel in 1963 was partly compensated by larger imports of 4,680 tons compared with 4,127 tons in 1962.

Nickel consumption in France rose again in 1963 to 15,172 tons compared with 13,099 tons in 1962 and 15,384 tons in 1961. Price of nickel at the beginning of 1963 was US$1.77 per kilogram.

Precious metals.—Salsigne was the only gold mine in France. The ore carried 10 to 12 grams of gold, (0.32 ounce), 20 to 35 grams of

Digitized by Google

silver (0.65 ounce), 400 to 450 grams of bismuth, and 2 to 2.5 kilograms of copper. Since 1905 this mine has produced more than 1.28 million troy ounces (40 metric tons) of gold, 3.2 million to 3.5 million troy ounces (100 to 110 tons) of silver, 7,000 to 8,000 tons of copper,[13] and 700 to 800 tons of bismuth. Gold was also recovered from imported ores. Lead-zinc ores, both domestic and imported, were the principal source for silver output in France. Penarroya's silver production in 1961 was almost 2.48 million troy ounces (77,114 kilograms) the same amount as the total reported for the country. Gold bearing concentrate was shipped to Sweden for recovery of the precious metals.

Re-export of gold shown in the mineral and metal trade table presumably refers to gold entering France for processing and reexport. Imports of precious metals other than gold in 1963 totaled 26,714,000 troy ounces (830,900 kilograms) valued at $42,640,000. The individual metals and their respective values were: Silver 26,543,600 troy ounces (825,600 kilograms), US$32,511,000; platinum group metals 170,400 troy ounces (5,300 kilograms), US$10,128,000. Exports were 2,945,000 troy ounces (91,600 kilograms) valued at US$6,199,000, of which silver accounted for 2,883,918 troy ounces (89,700 kilograms) and US$2,401,000.

Tin.—Since 1960 tin concentrates have been obtained from St. Renan in Brittany which was exploited initially by hydraulicking and in 1963 by dredging. The deposit was prospected and explored by Bureau de Recherches Géologiques et Minières and Société Americaine de Prospection et d'Études Minières which together formed the Campagnie Minière de Saint-Renan to work the deposit. Reserves are estimated to total 8 million tons of gravel with 600 grams of tin per cubic meter. Production of about 5,000 tons of concentrate during 1947–57 was obtained from the Abbaretz deposit also in Brittany. Tin concentrate has been shipped abroad for smelting because France has no tin smelters. Tin recovered from scrap totaled 400 tons in 1962 and was used mainly in the chemical industry and for making alloys.

Consumption requirements have been met by metal imports, which totaled 11,252 tons in 1963. Tinplating accounted for 57 percent of consumption in 1962; other important end uses were solder 21 percent, bronzes 8 percent, and antifriction metal 5 percent.

Tungsten.—Le Montmins mine, the last French property producing tungsten, was closed at the end of 1962, having produced 624 tons of concentrate with 67 to 72 percent WO_3 during that year. France produced 13,500 tons of concentrate during 1943–62 from a number of mines of which Le Montmins was the most important.

Consumption in 1962 was 2,361 tons of concentrate of which 1,760 tons was used in the ferroalloy industry and the remainder for other purposes.

Uranium and Other Atomic Energy Minerals.—The Commissariat à l'Énergie Atomique (CEA) produces directly natural uranium, thorium, plutonium, and lithium. Independently or in collaboration with industry, it produces graphite, zirconium, and beryllium. As of 1963, heavy water and enriched uranium were not produced. Completion of the Pierrelatte gas diffusion plant for separation of U^{235} will

[13] Rouveyrol, P. L'Or en France (Gold in France). Mines et Métallurgie, No. 5, May 1964, pp. 237–238.

Digitized by Google

supply enriched uranium. The initial phase of this plant is due for operation in 1964.

TABLE 19.—Production of uranium concentrate

(Metric tons)

	1961	1962	1963
Concentrate:			
Domestic ore	2,936	2,181	2,101
Imported ore	484	1,863	2,541
Metal content:			
Domestic ore	1,128	1,035	1,022
Imported ore	118	486	507
Total metal content	1,246	1,521	1,529

In 1962 there were 17 active mines and some ore was obtained from exploration and development. The CEA was the largest ore producer in France, accounting for 87 percent of the 1962 output. Haute Vienne, Loire Atlantique, and Loire Départments produced 38, 20, and 15 percent, respectively, of total ore output.

Purchase of uranium ore from private producers since July 1, 1962, has been governed by new contract terms published in July 1961, which were to be valid until December 31, 1966. Under the new terms, the lower limit of ore grade is 1.5 parts per thousand instead of 2 parts per thousand of uranium content. Price of the ore is set by the formula (grade of ore in parts per thousand minus 1) times $8.10 per kilogram of contained uranium, with an upward limit of $8.10 per kilogram of contained uranium for ore with more than two-thousandth uranium. Uranium concentrate is produced from domestic and imported ore by the CEA and private companies.

In 1962 CEA produced roughly half of the concentrate (metal content) and private industry produced the remainder; however, private industry obtained most of its concentrate from imported ore. The concentrate was produced in five mills.

TABLE 20.—Uranium mills

Name and locations	Rated annual ore treating capacity (metric tons)	Remarks
Société Industrielles des Minerais de l'Ouest:		
Bessines near Limoges	400,000	Produces magnesium uranate by sulfuric acid treatment and ion exchange or solvent extraction. Ore is obtained from mines of La Crouzelle Division. In 1962, 400,000 tons of ore treated.
L'Ecarpière	300,000	Treats ore from Vendée Division and from private mine in Brittany to produce magnesium uranate; in 1962, 305,000 tons of ore treated.
Commissariat L'Enérgie Atomique:		
Guegnon (Saone et Loire)	(1)	Treats concentrates produced in Mouanna in Gabon. In 1962 plant treated 1,320 tons of concentrates.
Bois-Noirs (Loire)	(1)	158,000 tons or ore treated in 1962. Uranyl nitrate is produced.
Le Bouchet	(1)	This plant treats urano-thorianite of Madagascar to produce sodium uranate.

[1] Data not available.

Digitized by Google

Natural uranium metal was produced in Malvesi and Le Bouchet, Le Bouchet, south of Paris, had a production program of 400 tons of uranium which was achieved in 1963; it also produced thorium. The plant in 1962 produced 144 tons of thorium nitrate and 22 tons of thorium hydroxide. In addition, facilities were planned for Le Bouchet to produce calcined UO_2 and granulated uranium trioxide as fuel elements. Malvesi was the larger production facility for natural uranium with an annual capacity of 600 tons (626 tons produced in 1962).

In 1962 about 100 tons of zirconium with less than 120 parts per billion of hafnium for nuclear use was produced by Nobel-Bezel in Cuise-Lamatte plant. Hafnium was recovered and concentrated to produce halfnium oxide with 94 percent metal.

Other Nonferrous Metals.—France consumes about 3,000 tons of antimony annually. No mine production has been reported since 1959, but the metal has continued to be recovered from imported ores at two plants, one in Mayenne and the other in l'Aisne.

Bismuth produced in France has been shipped abroad for refining. Domestic smelter production supplies only about one-tenth of requirements.

Cobalt consumption in 1962 was reported at 390 tons compared with 480 tons in 1961 and 670 tons in 1960. Local production by and large covers requirements.

NONMETALS

Besides building materials and quarry products, France produces a fair range of nonmetallic minerals, but for many items, such as asbestos, barite, borates, cryolite, industrial diamonds, dolomite, graphite, magnesite, mica, phosphate rock, and pyrite, it has depended partly or entirely on imports. During 1959–62 there has been a continuous upward trend in production of the raw materials of the building industry. In spite of the severe winter, rate of activity in homebuilding and public works increased 7 percent in 1963, a fact which must have helped sustain the upward trend. Similarly, sulfur production has increased at a rapid rate and is believed now to be at an optimum rate; salt production also has increased. Significant production trends in other commodities were not apparent.

The value of nonmetals produced in 1962, exclusive of building raw materials and quarry products, totaled about US$142 million. Potash, salt, and sulfur accounted for 60 percent, 18 percent, and 16 percent, respectively, of the total value. Building raw materials and quarry products were valued at US$344 million, of which US$41 million was accounted for by materials used in industry, about US$4 million by materials used in agriculture, and US $299 million by the building industry, including sand and gravel (US$108 million), other building materials such as stones, clays, cement, limestone, and gypsum US$102 million, and material for roadbuilding and similar uses US$89 million.

In 1962 France was a net exporter of cement, chalk, crushed rock and gravel, diatomaceous earth, fluorspar, gypsum, kaolin and refractory clay, lime and limestone, marble and other building stones, potash, salt, sand, sulfur, and talc. Import and export value of nonmetals, including cement, totaled $98 million and $101 million, respectively.

Digitized by Google

Trade in slag and ashes including Thomas slag, added US$15 million to imports and US$11 million to exports. Among imports, phosphate rock (US$29,472,000), asbestos (US$16,441,000), Thomas slag (US$9,074,000), clays (US$8,430,000), and pyrite (US$5,096,000) were the most important. Potash, cement, and sulfur exports were valued at US$40 million, US$17 million, and US$13 million, respectively.

Cement and Lime.—In 1963 France ranked sixth as a world cement producer; it was third in the Common Market after West Germany and Italy. At the beginning of the year there were 61 plants in operation with an aggregate capacity of about 19 million tons. Of the 61 plants, only 5 had an annual capacity of less than 100,000 tons and these plants contributed only 1.6 percent to the 1962 output. Fifty plants ranged in capacity from 100,000 to 500,000 tons and together accounted for 76.4 percent of output. Six plants had capacities exceeding 500,000 tons per year and produced 22 percent of the 1962 output. Average annual production per plant in this year was 275,000 tons compared with 140,000 in 1952. The turnover of the industry in 1962 was equivalent to US$263 million. The capacity was expected to increase to 22 million tons in 1964.

Cement production has grown in the last decade, sustained by public works and new dwellings of which 3.5 million were built between 1945 and 1962. Nevertheless, France ranked sixth in Europe in construction of new dwellings.[14] The fourth plan envisages building 1.3 million new dwellings during 1961–65.

Production in 1963 was 6.5 percent more than in 1962 and 90 percent more than 1952; plants operated at 86 percent capacity (87.6 percent in 1962). As a result of the extreme winter, industry suffered a production loss of approximately 900,000 tons in January and February compared with a similar period in 1962, so that the production gain for 1962 was less than the 7.5 rate of increase for 1962 and 1961. The production target for 1965, according to the fourth plan, is 19.5 million tons per year.

About 70 percent of the 1962 output was portland cement and 17 percent was metallurgical cement. In the same year 2,875,000 tons of blast furnace slag was used, 260,000 tons more than in 1961. Fly ash consumption reached 390,000 tons in 1962 against 330,000 tons in 1961.

France shipped 16,950,000 tons of cement to the domestic market in 1963, 15,630,000 tons in 1962 and 14,440,000 tons in 1961. Per capita consumption for the whole of France in 1963 was 352 kilograms compared with 479 kilograms in West Germany and 438 kilograms in Italy. In 1962 per capita consumption in the Mediterranean area of France was 481 kilograms followed by the Southeast with 415 kilograms. The Paris region was the largest consuming area with 2,722,000 tons, followed by Nord and Pas-de-Calais with 1,225,000 tons, East 1,086,000, Rhône-Isère-Savoie 931,000 tons, and Bouches-du-Rhône 656,000 tons.

Cement imports have been small and have had no great impact on the French cement market. In 1963, 67,957 tons of cement and clinker were imported—32,202 tons from Belgium-Luxembourg, 13,173 from West Germany, 10,400 tons from Italy, and the remainder from other European countries. French cement exports were 1,081,334 tons,

TABLE 21.—Cement production by types

(Thousand metric tons)

	1959	1960	1961	1962
Portland	8,990	9,281	9,607	11,757
Slag	2,566	2,381	2,837	2,203
Special	1,166	1,130	1,860	1,475
Other slag cements	738	865	404	626
Total	13,460	13,657	14,708	16,061
Natural cement	175	121	177	397
Mortar cement	364	381	496	424
Total	13,999	14,159	15,381	16,882

including 440,544 tons to West Europe (West Germany 248,332, Italy 54,103), 508,313 tons to Africa (Ivory Coast 159,978, Dahomey 55,207, Cameroon 58,517, and Gabon 22,466).

The industry invested $27.5 million in 1962 (exclusive of $3.5 million absorbed in the building of a new plant) and planned to invest $29 million during 1963. Total investments in 1962 equaled 12 percent of the turnover. The investment program during 1962 and 1963 called for construction of a new plant, replacement of 10 old kilns in existing plants by 8 new kilns, and addition of 2 new kilns also in existing plants. As part of the 1963 modernization program seven new kilns were built: Two dry kilns, four wet kilns, and one vertical kiln.

Société des Ciments Français with 11 plants throughout France, Ciments La Farge with 11 plants including 5 in southeast France, and Établissements Poilet et Chausson with 6 plants mostly in northern France together probably controlled half of the country's production. Gargenville and Beffe of Poilet et Chausson are two of the largest plants. Areas of large plant concentrations are Pas-de-Calais and Aisne Départements where chalk and clayey limestones are used as raw materials; Seine-et-Oise where chalk and clay are used; and Moselle where limestone and blast furnace slags are used. In southeast France plants are in Isère, Savoie, Bouches-du-Rhône, Gard, Ardèche, Drôme Départements, and others. Some seven or eight plants are scattered in western France. As of January 1963, the geographical distribution of cement production capacity in percent was as follows: Nord and Pas-de-Calais Départements, 16.2; Paris and Paris basin area, 21.5; Southeast, 20.9; Mediterranean, 13.4; Southwest, 12.1; East, 11.7, and West, 4.2.

Fuel and electricity consumption of the cement industry in 1962 with 1961 consumption in parentheses were as follows: coal 2,350,000 tons (2,300,000); fuel oils 320,000 tons (260,000); natural gas 170 million cubic meters (150 million); electricity 1.46 billion kilowatts (1.36 billion).

The industry employed 13,400 workers in 1963. Labor cost was estimated at 30 percent of production cost, fuel and energy cost at 50 percent, and other costs at 20 percent. Cement prices were increased 3.5 percent in May 1962 and the 1963 lime price index was 115 based on 1958 prices as 100.

Nearly three-fourths of the hydraulic lime output of France was produced by some 40 cement plants. The remaining fourth was pro-

Digitized by Google

duced by about 40 lime burners which do not make any cement. Geographical distribution of lime producing capacity in percent as of January 1, 1963, was as follows: Paris and Paris basin, 20.1; Southwest, 31.4; Southeast, 22.5; East, 7.4; Mediterranean, 6.8; West, 5.2; Massif Central, 2.5; and Nord and Pas-deCalais Départments, 3.2.

High-purity or fat lime (chaux grasse) was produced by a number of large plants which, except for one, were integrated with iron and steel, ferroalloy, or chemical industries to which they deliver their output. Eight of these plants were in the Meuse area. In addition, there were a number of small plants with an annual production of less than 5,000 tons distributed fairly widely.

Construction Materials and Quarry Products.—In 1963 raw materials for the manufacture of cement, lime, plaster, brick, tile, ceramic and refractory materials, and building stones were produced in sufficient quantities to meet the country's requirements and to leave an exportable surplus for a number of commodities. The 1962 output comprised about 43 million tons of building materials; 75 million tons of sand and gravel; 45 million tons of road and foundation building material; 26 million tons of material for the industry such as kaolin and refractory clays, limestone, glass and foundry sands, limestone for the cement and steel industry, chalk, barite, and others; and 1,250,000 tons of materials for soil improvement and other agricultural uses, including limestone, gypsum, marl, phosphate, and phosphatic chalk.

Available preliminary data indicate increases in 1963 monthly average production for flux limestone, alluvial sand and gravel, industrial sand, road building materials, cement, and hydraulic lime.

The industry employed 87,100 persons, of which 74,600 received hourly pay and the remainder were salaried employees. This figure does not include workers in limestone and clay quarries which were captive operations of the cement plants. L'Union Nationale Interprofessionalle des Matériaux de Construction et Produits de Carrières is the industry's professional organization.

TABLE 22.—Size of quarry and sand and gravel operation in 1961 [1]

(Number of employees)

	0 to 5	6 to 10	11 to 20	21 to 50	51 to 100	101 to 200	201 to 500
Sand and gravel	808	281	199	103	12	2	3
Industrial sand	105	29	13	11	1	1	----
Road building materials	578	307	265	115	20	9	----

[1] Annuaire Statistique de la France, 1963.

A large variety of building stones are available throughout the country so that most Départements are not far from a source of building stones. Similarly, plants utilizing quarry products are generally close to the source of raw materials and products are not transported more than 250 kilometers from producer to the consumer. The majority of the quarries and sand and gravel pits are small.

Fluorspar.—France regularly has produced enough fluorspar to meet its own industrial needs and to have a surplus for exports which comprises mainly metallurgical grade fluorspar to West Germany and

Digitized by Google

acid grade to the United States. It is estimated that of the 1962 output, 65,000 tons was flotation concentrate, 98 percent CaF_2, and the remainder cleaned and cobbed ore of about 60 percent CaF_2.

The French steel industry used 32,574 tons of fluorspar in 1963. Annual fluorspar consumption in France was reported at 132,000 tons:[15] 60,000 tons by the metallurgical industry, 65,000 tons by the chemical industry, and 7,000 tons by the ceramic industries. Of the chemical grade, the aluminum industry used 67 percent, and the remainder was used for making various fluorine chemicals. Of the quantity used by the metallurgical industry, 33,000 tons were used in steelmaking and the remainder for making ferroalloys.

At the end of 1962 there were 24 operating fluorspar mines: 11 in the Massif Central, 3 in Tarn, 6 in Var, 1 in the Vosges, and 3 in the Pyrénées-Orientale Départements. Of the 24 mines, 1 produced 75,000 tons or 38 percent of 1961 output; 15 had an annual production less than 5,000 tons, 3 from 5,000 to 10,000 tons, and 5 from 10,000 to 20,000 tons. The Massif Central area is no longer dominant in the output because of mining[16] in the Départements of Tarn and Var.

There were flotation plants at Chambarel near Le Barlet mine, La Bastide near the Escaro mine, and at Orbiel, Les Arcs, and Langeac.

TABLE 23.—Production of fluorspar ore by areas

(Metric tons)

Area	1959	1960	1961	1962
Massif Central (Départements of Ardèche, Aveyron, Indre, Haute-Loire, Nièvre, Puy-de-Dôme, Haute-Saône, and Saône-et-Loire.)	33,499	47,800	41,157	84,405
Tarn	26,712	28,073	28,004	26,558
Alpes-Maritimes				5,234
Creuse	1,773	1,160		124

Potash and Other Fertilizer Materials.—In 1963 France produced 16 percent of world potash, ranking behind the United States, the Federal Republic of Germany, and East Germany. Production and sales were about the same as in 1962. Bromine was recovered as a byproduct of potash; output was determined by the 1,600 tons sold.

Consumption of compound fertilizers in the fertilizer year 1962–63 (July 1 to June 30) was 561,500 tons of K_2O compared with 549,270 tons of P_2O_5 and 236,960 tons of nitrogen. The corresponding consumption figures for 1961–62 were 504,620 tons of K_2O; 489,890 tons of P_2O_5; and 216,260 tons of nitrogen. In 1962–63 consumption of compound fertilizers was 62 percent of total consumption for potash, 49 percent for phosphate, and 35 percent for nitrogen fertilizers.

France exported 73,198 tons of crude potash in 1963, mainly to Belgium-Luxembourg and the Netherlands, and 1,238,000 tons of potassic fertilizers to the following destinations: West Europe 768,445 tons (Belgium-Luxembourg 198,997, United Kingdom 197,742, Switzerland 71,035, Ireland 60,495, the Netherlands 56,931, Italy 43,357); the United States 142,714; Japan 122,639; and Ceylon 41,225.

The Government-controlled Mines Domaniales de Potasse d'Alsace (MDPA), has been the sole potash producer because since 1959 the privately owned mines of Kali Sainte-Thérèse have been absorbed in the MDPA and mines near Dax in southwest France were closed in that year. All the potash is marketed by the Société Commerciale des Potasses Alsace. A research center, Centre de Recherches de la Société d'Etudes Chimiques pour l'Industrie et l'Agriculture was established by MDPA in 1959.

During 1945–62 about US$200 million was spent to modernize mining and beneficiation of the Alsace potash mines and to increase their production capacity. All mine shafts were equipped with skips, bringing total hoisting capacity to 45,000 tons per day. Underground haulage was improved by introduction of larger mine cars and belt conveyors. Mining was increasingly mechanized and room and pillar method was introduced some years ago. The share of this mining method in total output has increased. Continuous miners have been introduced in some places.

TABLE 24.—Principal potash mines in Alsace

(Metric tons)

Name of mine	Production K_2O content of mine run ore in 1962	Remarks
Amélie	1,031,989	Average daily production of ore was 8,500 to 9,000 tons.
Théodore	237,445	New flotation plant in 1960 with about 250 tons/hour capacity.
Théodore I	45,305	
Marie	156,945	
Anna	52,262	
Anna I	57,191	
Joseph	98,198	
Prince Eugene I	33,406	
Marie Louise, Marie I, Max, and Fernand	19,279	

Potash (K_2O) was recovered by hot leach, flotation, and levigation. The share of ore treated by flotation increased. Of the 1,655,543 tons of K_2O equivalent produced in 1962, 1,110,623 tons was from hot leach, 478,490 tons from flotation, and 66,430 tons by levigation. A plant for producing potassium carbonate and potassium bicarbonate was put into operation in 1962.

Salt.—Of the salt produced in 1962, 54 percent was from brines of saline springs in Lorraine and 30 percent from marine marshes, almost entirely from along the Mediterranean. The salt from brine wells was used entirely as dissolved salt in the chemical industry, mainly for making sodium carbonate. Of the 1,267,282 tons of marine salt, 646,246 tons were used for industry and agriculture, 158,977 for

Digitized by Google

domestic consumption, 6,445 tons for fisheries, and 18,057 tons were exported.[17]

Crude rock salt, mined near Nancy, was used in agriculture (30,666 tons), chemical industry (53,013 tons), and export (60,543 tons). Rock salt is also mined in Franche-Comte region in mines near Besancon and Lons-le-Saunier and in the southwest region Départements of Haute Garonne, Landes, and Basse Pyrénées. The rock salt from these two regions is reported as refined salt.

Household consumption accounted for 187,405 tons of the refined salt; industry, agriculture, and fisheries for 332,701 tons; 20,791 tons were exported. It is not known whether all of the refined salt reported was obtained from rock salt.

France imported 62,709 tons of salt in 1963 (37,720 tons from Algeria, 17,486 from Tunisia, and 9,501 from West Europe) and exported 137,265 tons of salt to the following destinations among others: Belgium-Luxembourg 92,235; West Germany 16,018; and African countries 5,113.

Sulfur and Pyrite.—Over 99 percent of the elemental sulfur output in France was recovered from the Lacq natural gas by Société Nationale de Pétrole d'Aquitaine (SNPA). Starting with output of 28 tons in 1957, sulfur production increased to 1,417,700 tons in 1963, making France an important world supplier.

Compagnie de Raffinage Shell-Berre produces relatively small tonnages from refinery gases; Nobel-Bozel also produces small tonnages. In 1962 Shell produced 3,070 tons and Nobel-Bozel 4,920 tons of sulfur; their total output in 1963 was about 9,500 tons.

During the year SNPA was building a sulfuric acid plant at Lacq to recover about 1.5 percent sulfur contained in the residual gases in the form of hydrogen sulfide and sulfur dioxide. Daily production will be 400 tons of 94 percent sulfuric acid.[18]

Sulfur consumption totaled 506,380 tons in 1962 distributed by consumers as follows: Sulfuric acid 320,850; agriculture 54,700; carbon disulfide 55,280; sulfur dioxide, sulfite products, and paper pulp 54,700. Production of sulfuric acid increased in 1963 to 2,395,000 tons from 2,214,000 tons, an increase of 8 percent, indicating a sulfur consumption in 1963 closer to a range of 530,000 to 550,000 tons.

Sulfur exports in 1963 totaled 1,012,000 tons, almost double the 1962 tonnage; in addition, 471,000 tons were supplied to the domestic market. With exports of 700,000 tons to West Europe, France was the dominant supplier in this area. Some destinations of French sulfur in 1963 and the corresponding tonnages were: West Germany 141,543; United Kingdom 198,216; the Netherlands 79,059; Sweden 51,119; Belgium-Luxembourg 43,142; African countries 124,617; Brazil 42,205. Sulfur imports were 115,021 tons, of which 67,927 tons were from Mexico and 44,620 tons from the United States.

Severe winter conditions affected pyrite production in the early months of the year resulting in smaller total production in 1963. Domestic production was supplemented by imports which were 395,622 tons in 1963. In 1962, 634,800 tons of pyrite were used for sulfuric acid production, and 4,800 tons were used to manufacture paper. Major pyrite users are in northern France.

In 1962, pyrite was produced in the following mines with their individual outputs in tons in parentheses: Chizeuil (84,370) and Saint-Bel (198,357). A 600-ton-per-day beneficiation plant with jig and flotation concentrates Chizeuil ore to a product with 45 percent sulfur.

MINERAL FUELS

Coal.—The severe winter of 1962–63 and the 33-day strike of March 1 to April 5 in the nationalized coal mines greatly influenced the industry and the coal market during 1963. The strike cost 5.3 million tons of coal production, but this was partially made up during the balance of the year. While production declined, apparent consumption rose 5 percent. The additional demand and lost production was met by imports which exceeded the 1962 imports by 6,305,000 tons and by withdrawal of about 2.5 million tons from stocks. Coal met 58 percent of energy requirements exclusive of gasolines. In absolute quantities the position of coal has slightly improved as an energy source, but additional energy needed has been supplied largely from other sources; thus, coal's share in total energy produced has declined.

TABLE 27.—Energy consumption by sources

Type of fuel	1959	1960	1961	1962	1963 [1]
Quantity:					
Solid fuel, million tons of standard coal equivalent	70.0	69.5	70.7	74.8	76.8

But for about 200,000 tons annually, all bituminous coal and anthracite in France were produced in mines which were nationalized in 1946. The industry was administered by Charbonnages de France, a public corporation with a 14-member board of directors under the joint control of the Minister of Finance and Economic Affairs and the Minister of Industry. Members of the board are designated by the Government and are drawn from Government, labor, and consumers. The corporation exercises general direction on the coal industry and coordinates activities of the individual basins, presents annual production plans to the Government for approval, and makes recommendations on coal trade. Charbonnages has established nine regional coal authorities known as houillères de coal mine basin which in turn are composed of 16 members representing Charbonnages, coal consumers, and labor. Each of these authorities has responsibility for the management of mines in its own region. In 1947 Charbonnages also created the Centre d'Etudes et Recherches de Charbonnages de France (Cherchar) for carrying out technical and scientific research.

Production.—An overall program, called the adaptation plan, announced by the French Government in 1960, set a production target of 53 million tons of coal in 1965. The target was fixed with the objec-

Digitized by Google

tive of closing marginal mines and making prices of French coal more competitive. The target for 1963, according to this plan, was 53.7 million tons, which was not achieved because of the miners strike. The output was equivalent to 62 percent of apparent consumption compared with 78.2 percent in 1962 and 77.8 percent in 1961.

The coal mines of Nord and Pas-de-Calais Départements, which account for nearly half of the national output, registered a production loss of 9.8 percent. The 7.9-percent loss in the Lorraine field, France's second largest basin, was below the loss for the industry as a whole.

TABLE 28.—Salient statistics of the coal and lignite industry

	1959	1960	1961	1962	1963
Coal:					
Production thousand metric tons	57,607	55,966	52,363	52,369	47,754

Based on data for 11 months of 1963, 28.9 million tons of the production was coking coal or 60 percent of total output (63.4 percent in 1962). Respective shares of Nord/Pas-de-Calais, Lorraine, and Centre-Midi in coking coal production in the first 11 months of 1963 were 43, 39, and 18 percent, respectively.

In 1962 there were 83 mines or mining centers in operation (120 in 1954) with 337 shafts of which 116 were hoisting shafts. Average mine depth was 533 meters. Of the total output, including waste mined with coal, 43.1 percent came from seams of less than 1.5 meters with dips up to 45° and another 42 percent from seams of 1.5 to 4 meters width with the same range of dips. Seams with dips less than 20° accounted for 53.7 percent of the output. In the same year two-thirds of the production was mined in longwall faces entirely within the footwall and hanging wall and much of the remainder was mined from thick seams which required use of slicing, cut and fill, or room-and-pillar mining methods. Sixty percent of the coal was obtained from faces which were allowed to cave after coal extraction. In spite of this, 13 million cubic meters of fill were brought into the mines—65 percent by hydraulic methods, 17 percent by mine cars and skips, and 18 percent in dry pipes.

TABLE 30.—Production of coal by mining methods

(Percent of total output)

Method of mining	1960	1961	1962
Pick hammers alone	34.4	31.3	29.0
Pick hammers and explosives	12.5	12.3	12.4
Coal cutters[1]	17.3	19.1	19.4
Explosives (shot from solid)	19.0	18.5	20.0
Plough and plough-scraper	12.1	13.3	13.1
High-pressure air-breaking with or without coal cutter	3.9	5.2	6.0
Other	.8	.3	.1

[1] Explosives and pick hammers are used for breaking down the coal.

Source: Charbonnages de France. Rapport de Gestion, Exercise 1962. Paris, 1963. 139 pp.

Mechanization of French mines has increased much during the last decade. A fully mechanized mine is defined as one where breaking and loading are mechanized [19] and a semimechanized mine is one where either mining or loading is mechanized.

In October 1963, 53.5 percent of coal mined underground was obtained from mechanized operations, and 28.5 percent was obtained from semimechanized operations. Corresponding figures for October 1962 were 50.5 and 27.2 percent and for 1953, 19.7 and 24.4 percent. In addition to modern equipment for coal faces, such as coal cutters, ploughs, and cutter loaders, the use of hydraulic and self-advancing steel props has been adopted.

In the mines of Charbonnages de France during 1962, for winning the coal there were 21,520 pneumatic picks (exclusive of drilling equipment used for drilling into rocks and coal), 241 longwall and other coal cutters, 40 chain shearing machines, 138 cutter-loaders, 150

[19] Winning of coal by pneumatic or electric-pick methods is not considered a mechanized operation.

Digitized by Google

coal ploughs, and 46 other types of cutter-loaders. For loading coal, 267 loaders, 53 chain conveyors, and 307 mechanized shovels were in use; for loading rocks, 128 chain conveyors, 536 mechanical shovels, and 6 other types of loaders were in use. Consumption of electricity underground (exclusive of use in exhausting) has grown from 1.82 kilowatt hours per ton in 1952 to 5.02 [20] kilowatt hours per ton in 1962. Capacity of transformers installed underground has grown from 106,910 to 340,928 tons during the same period.

TABLE 31.—Status of mechanization of coal, October 1963

	Average number of operating faces	Average daily production all faces (metric tons)	Average daily production per face (metric tons)	Average length (meters)	Average face advances (centimeters)

Thanks to the coal plough, the Nord/Pas-de-Calais Basin's share of coal from mechanized mines increased from 43 percent in October 1962 to 46.6 percent in October 1963. In this area, 95 faces have a plough and one-fourth of the basin's production is obtained by its use. Semimechanized operations accounted for one-third of the production in the same period. Lorraine, the most mechanized basin, produced 86.9 percent of its output in October 1963 from mechanized faces compared with an 83.8 percent production for the same month in 1962. Centre-Midi remained poorly mechanized with a 27.7 percent output in 1963.[21]

Replacement of small operations with long faces results in a statistical increase in average length of face and decrease in advance. For all underground mines, average length was 106 meters in October 1963 compared with 102 meters in 1962; corresponding figures for Lorraine were 156 and 142 meters. Daily advance was 104 centimeters in 1963 and 105 centimeters in 1962 with 55 and 61 centimeters, respectively, for the Lorraine Basin. Number of working faces was reduced from 929 to 887 but daily production increased from 175,506 to 177,540 tons. As a result of lengthening working face and increasing mechanization, production per working face increased from 189 tons in October 1962 to 200 tons a year later.

As a result of mechanization, productivity has improved. Increase in underground productivity per man-day in 1963 compared with 1962 figures was highest in Lorraine (95 kilograms), followed by the Nord/Pas-de-Calais area (30 kilograms) and Centre-Midi Basins as a whole (20 kilograms). Because the coal is deteriorating with depth and because there have not been sufficient qualified workers, there has been a relatively small increase in production in the Nord/Pas-de-Calais Basin.

Production cost of coal in 1962 was US$15.98 per ton compared with US$15.24 per ton in 1961. The 1962 cost was composed of labor US$10.53, supply US$2.9, and overhead, taxes, and amortization US$0.95. Fringe benefits in the year were equal to 98.97 percent of wages. Price received per ton in 1962 was US$13.42 so that the Charbonnages de France's loss in the year amounted to $83,529,250 compared with $53,191,750 in 1962 and $6,269,750 in 1959.

Consumption.—Actual consumption of coal in 1963 must have exceeded apparent consumption, as was the case in 1962 when the former was estimated at 75 million tons. Consumption was at record high in 1956 and 1957, at 78 and 78.5 million tons, respectively.

TABLE 33.—Average output per man-shift in principal coal basins (bituminous and anthracite)

Powerplants, the iron and steel industry, domestic users, and industry other than iron and steel were the four principal consumers of French coal. Total sales of solid fuels in 1963 probably exceeded the 1962 figure of 61 million tons. Of the coal which was produced and imported in 1963, 41 million tons were transformed as follows, into electricity, coke, and briquets, in thousand tons: Electricity 15,600, coke 17,700, and briquets 7,600.

Consumption by the iron and steel industry has been influenced by variation in steel output and by reductions in coke consumption per ton of pig iron produced; consumption decreased from 967 kilograms in 1961 to 846 kilograms in 1963.

In industries other than iron and steel and small industries, the share of total energy needs supplied by solid fuels has decreased from 58.6 percent in 1960 to 49.7 percent in 1962, whereas that supplied by fuel oil increased from 8.5 to 40.4 percent and that supplied by natural gas increased from 1.6 to 9.9 percent during the same period. To encourage use of coal by industry, a central steamplant was put into operation at the end of 1962 to supply steam for heating to a number of industrial consumers of gases. The installation supplies steam to users at a cost lower than could be obtained from smaller individual plants.

Source: Bulletin de la Chambre Syndicale de la Sidérurgie Française, No. 144, 1963, pp. 11–12.

Domestic users, including small-scale industry, remain an important market for coal, especially when a winter is colder than normal. Sale of all solid fuels, including coke, semicoke, and briquets, to this consumption sector increased from 16 million tons in 1961 to 18 million tons in 1962 because of the severe winter 1962-63.

Consumption by the railroads and gas producers has diminished, first because of the rapid electrification of French railroads and secondly because of inroads made by natural gas and gases that were made from petroleum products. In 1962, Gas de France closed 18 installations producing gas from coal. By contrast, 208,000 tons of petroleum products was used during 1962 for gas generation compared with 145,000 tons in 1961. Distribution of total gas supply in 1962 by production method (in percent) was gas from coal 42, natural gas 42, refinery gas 7, and liquefied gas 9.

Coal and lignite consumption by Electricite de France increased from 6.2 million tons in 1961 to 8 million tons in 1962 when 57 percent of the 82,300 million kilowatts produced was from thermal plants. Of total power produced by standard thermal powerplants in 1962 69 percent was generated through use of coal and lignite as fuel; 11 percent each through use of natural gas (from Lacq) and petroleum; and 9 percent through use of manufactured gas.

The severe winter and shortfall of domestic production increased coal imports in 1963 by 44 percent. The Common Market countries supplied 52 percent of the imports. Germany, including the Saar, ranked first among Common Market as well as world suppliers. Shipments from the United Kingdom and the U.S.S.R. increased substantially from 1962, when imports were 791,000 and 947,000 tons, respectively. Imports from the United States were 178,000 tons more than the previous year. France was not a large exporter of coal; exports totaled 983,000 tons in 1963. Principal destination and quantities in thousand tons were: West Germany 544; Belgium 278; Switzerland 288. All coal imported from countries other than those in the Community are handled by Association Technique de l'Importation Charbonniere.

Digitized by Google

Prices of coal in U.S. dollars per ton f.o.b. mines of Nord/Pas-de-Calais as of June 1963 were in the following ranges depending on size: Anthracite (with volatile matter less than 10 percent) 29 to 31.50; anthracite coal (10 to 14 percent volatile matter), 22 to 29.50; low-volatile coal (14 to 18 percent volatile matter) 17 to 25; coal with volatile matter more than 18 percent, 15 to 17; and high-volatile coal (more than 30 percent) 15 to 17.50. For the whole bituminous coal group, price of fines varied from US$11 to US$15 per ton f.o.b. mines. Seasonal price adjustments are made with small discounts during off seasons and premiums during cold months.

TABLE 36.—Imports of coal, coke, and coal and lignite briquets in 1963

[1] Includes 15,000 tons of coke from Italy.

Source: Bureau de Documentation Minière. Combustibles Minéraux Solides. Statistique Annuelle Définitive, 1963. Pt. 2.

Stocks of coal have shown a steady decline since 1960. Of the 1963 stocks, 896,000 tons was marketable coal and 4,958,000 tons low-value coal.

Preparation.—Coal washing capacity in 1962 was 22,700 to 24,000 tons of coal per hour of which 19,300 tons were in new or modernized plants installed since 1946. Ratio of mine-run coal to marketable coal in the same year was 1.585 to 1 and nearly 32 million tons of waste were rejected by washing. During 1952–62 share of washed coal in total output increased from 72 to 86.3 percent. During the same period, heavy media separation (with magnetite the commonest medium) and flotation methods gained in importance at the expense of jigs, penumatic tables, and rheolaveurs.

As of 1962, coal supplied to coke ovens, domestic users, and patent fuel producers had an ash content not exceeeding 9 percent. Nut size coal is treated in heavy media units. For washing of fines from 0.5 to 10 millimeters, majority of installations use pneumatic jigs but there is a tendency to use magnetite cyclone. Flotation is used for sizes less than one-half millimeter; 4 million tons of flotation concentrates are produced annually.

Manpower.—Number of underground and surface workers of coal and lignite mines has shown a continuous decline. However, the rate of reduction of underground workers slowed down in 1962 and 1963 to 2 percent of the labor force engaged in the corresponding previous

year compared with 8 percent in 1961 and 6 percent in 1960. Reduction of surface workers, resulting largely from concentration of surface installations, remained about 5 percent in 1962 and 1963.

The reason for the strike of March 1 to April 5 was the miners' estimate of a lag between wage levels in public and private industry. The Government established a fact-finding committee to examine the relationship of wage levels in the principal nationalized and public enterprises to those in the private sector. On the basis of the committee's findings, the Government offered the miners an increase of 6.5 percent effective April 1, 1963, to be raised by stages to a total of 12.5 percent by April 1, 1964. Essentially, this wage package plus a small cash payment and assurance of the equivalent of a 4th week of vacation, were accepted.

Aside from the creation of a committee to compare coal industry wages with private industry wages, the Government appointed a Secretary General for Energy in charge of coordinating the energy industries and created a commission comprising representatives of Government, coal industry, and labor to study the future of the industry.

Patent Fuels.—Production of patent fuels increased substantially in 1963 because makers of patent fuels other than mines doubled their output presumably from imported coal. Of the 1963 output, 6,681,000 tons was classified as boulet (egg-shaped agglomerates used for domestic heating), 1,029,000 tons was special agglomerates which have been favorably received by consumers and 289,000 tons was briquets specially for industrial use.

Lignite.—Charbonnages de France was the largest lignite producer but Électricité de France operated Hostens and Arjuzanx mines in the Landes region of southwest France, using lignite for power production. These are open-pit operations with highest productivity in France. Mines of Charbonnages de France are in Provence in southeast France; these mines together with other small mines accounted for two-thirds of the 1963 lignite output. Lignite shipments to users other than mines' own use and briquetting plants totaled 1,795,000 tons; 843,000 tons to power plants; 819,000 tons to industry, and 133,000 tons to domestic users and small industry.

Coke.—France was not self-sufficient in coke. Capacity for producing coke including semicoke in 1962 was 24,300 tons per day; this figure includes the Carling coke batteries which were put in operation in March 1962. Coke for the steel industry was supplied from the industry's own coke ovens, from coke ovens of Charbonnages de France,

and from imports, mainly from West Germany including the Saar region. Mines in Nord/Pas-de-Calais produced nearly 1.8 times as much coke as the Lorraine mines. Although 67 percent of the 13,619,000 tons of coke received by the steel industry in 1963 was made in France, all of this coke was not produced from French coking coal. Of the 18,220,000 tons of coal charged to coke ovens in 1963, 33 percent was foreign coal. This was more than the 26 percent average for the previous 4 years because of the strike in 1963.

Much of the early effort of the Centre d'Études et Recherches des Charbonnages de France (Cherchar) in the field of carbonization was devoted to improving the domestic coking coal supply position by

blending increasing proportions of relatively poor coking coals of Lorraine with domestic and imported coking coal. In 1960 it was reported that four commercial plants were using the "stamped charged" method of charging coal to coke ovens. This procedure developed by Cherchar, improves the quality of coke produced from a given blend or produces the same quality coke, using less of the strongly coking coal in the blend. The use of semicoke or char to replace coking coal in the blend and the preheating of coal prior to charging into the oven are other approaches which have been investigated in the last 2 or 3 years.

Coal Chemicals.—Increase in production of coal chemicals in 1962 resulted from planned expansion of the coke producing capacity. However, as in other countries, coal chemicals are having difficulty in maintaining their competitive position with natural gas for making nitrogen fertilizers and with petroleum for making aromatic and other organic chemicals. Consequently, prices of coal chemicals have generally dropped, influencing adversely the economics of coke oven plants.

Petroleum and Natural Gas.[22]—Domestic production of crude petroleum in 1963 was 5.4 percent of the refinery throughput. Consumption of petroleum products attained a record of 36 million tons. Two new refineries which came on stream in 1963 added 6 million tons to the annual refining capacity which stood at 51.8 million tons at the end of 1963. Significantly, these refineries as well as the one at Feyzin, which is to come on stream in 1964, were all inland. Imports of crude petroleum from the franc area increased at the expense of imports from the Near East which in the past had constituted the bulk of the French supply. Cost of net imports of petroleum and petroleum products totaled US$450 million. Petroleum products supplied 35.9 percent of the 1963 energy requirements, and together with natural gas they supplied 40.6 percent. Tempo of exploration was less than in the previous year but development drilling increased. The recoverable reserve was 28 million tons (202 million barrels).

Government Activity.—The French Government was a petroleum producer, refiner, and distributor of petroleum products. The Régie Autonome de Pétrole was set up by a decree of July 29, 1939, to exploit the Saint-Marcet natural gas discovery. The Bureau de Recherches Pétrolières (BRP), set up by the Government in 1945, has majority interest in a number of companies of which the following companies were active in exploration and production in France: Compagnie d'Exploration Pétrolière (CEP), Compagnie des Pétroles France-Afrique (COPEFA), Société de Prospection et d'Exploitation Pétroliéres en Alsace (PREPA), Société Anonyme Française de Recherches et d'Exploitation de Pétrole (SAFREP), Société Nationale des Pétroles d'Aquitaine (SNPA), and Société Nationale de Recherche et d'Exploitation des Pétroles en Algérie (SNREPAL). Bureau de Recherches Pétrolières carried out 55 percent of exploration and 50 percent of the total drilling in 1962; it also produced 17 percent of the oil and 94 percent of the natural gas for the country.

[1] Data not available.
[2] Provisional.

The competitive position of crude tar has deteriorated because refinery asphalts are making inroads into crude tar markets for road use and because distillation of crude tar is not always economically advantageous. During the first quarter of 1962, stocks of benzene obtained from crude light oil (crude benzol) increased to about a quarter of national output so that tariff and other measures were necessary to improve the situation during the second half of the year. In 1962, Société Nationale des Pétroles d'Aquitaine put into operation a 70,000-ton-annual-capacity benzene plant, using petroleum feedstock as a base. This increased the potential capacity of benzene from

Digitized by Google

petroleum to about 80,000 tons per year, the same capacity as for coal. In 1962 coal mines and their associates, using coke oven gas as synthesis gas, produced 438,000 tons of ammonia (47.5 percent of national output) and 343,000 tons of nitrogen fertilizers (40.5 percent of national output). Corresponding figures in 1961 were 410,000 tons of ammonia and 328,500 tons of nitrogen fertilizer.

Exploration.—At yearend 128,700 square kilometers of area in France were covered by exploration and exploitation permits, compared with 128,500 square kilometers in 1962 and 130,800 in 1961. As of the end of 1963, 20 companies had exclusive permits or had requested exclusive permits for petroleum and gas exploration in France covering a total area of 160,796 square kilometers. Among these firms were the following with their respective areas in square kilometers: Société Nationale des Pétroles d'Aquitaine 30,453; Régie Autonome des Pétroles 28,906; Compagnie d'Exploration Pétrolière 18,045; and Société Esso de Recherches et d'Exploitation Pétrolières 11,622. The first three companies which are Government owned accounted for 48 percent of the area.

The number of exploration wells drilled in 1963 increased but development well drilling and geophysical activity decreased. Depth of all wells drilled (excluding shallow depth core drills) during the year was 236,000 meters, 8 percent less than in 1962.

TABLE 41.—Summary of drilling activities

Paris Basin	----	----	----	28	16,110
Aquitaine Basin	----	----	----	3	1,805

[1] Excludes two dry wells not reported by basin in 1962 detail.
[2] Revised data, apparently including two additional wells, totals 82,000 meters drilled, but breakdown by basin was not reported.
[3] Excludes shallow depth core drills.

Crude Oil Production.—In 1963, 77.6 percent of the output was obtained from the Aquitaine Basin. Société Esso de Recherches et d'Exploitation Pétrolières was the largest producer with 74 percent of the country's output, mainly from Parentis and Cazeux fields in Aquitaine, followed by Compagnie d'Exploration Pétrolière with 11

Digitized by Google

percent. Six other companies accounted for the remainder of the output.

At the end of 1962, there were 36 producing fields in France: 15 in the Paris Basin, 11 in Alsace, and 10 in Aquitaine. Only 16 fields produced more than 100,000 barrels during the year. There were 384 oil wells in these fields—42 producing under natural pressure, 270 pumped, 1 gas lift, 54 closed and 17 abandoned. Of the flowing wells, 34 were in the Aquitaine Basin.

Most of the oil-bearing rocks are limestone and dolomite and anticlines are the commonest oil-bearing structure. Production by oil-bearing zones in 1962 was as follows: Middle Jurassic 16 percent; Upper Jurassic and Lower Cretaceous 78 percent; and Upper Cretaceous and Tertiary 6 percent. Gravity of French crudes varies from 20° to 41° API, but Parentis and Cazeux fields, which together accounted for 65 percent of 1962 output, have 32.7° API gravity oil.

Trade.—Imports of crude oil from Algeria continued its increase, although at a smaller rate. This country, which was the principal producer in the franc zone, contributed 35 percent of total imports. In tonnage, the Middle East remained the largest supplier with 53 percent of the total, although in 1959 this area shipped 85 percent of total French imports. Cost of crude imports was US$821,917,000. France had a net export of 3,730,400 [23] tons petroleum products with a net value of US$174,900,000.

Fuel oils have constituted the most important imports—60 percent of total in 1963. Although 1963 fuel oil imports were exceptionally high, they have increased every year since 1959. Among the suppliers, U.S.S.R. and Rumania increased their exports substantially in 1963.

Of the 8,006,400 tons of products exported, 1,719,600 tons were shipped to the franc zone; 477,500 tons of gas oil; 368,600 tons of motor gasoline; 355,000 tons of heavy fuel oils; 95,400 tons of lubricants;

Digitized by Google

156,100 tons of kerosine and white spirits; 79,600 tons of asphalt; and 53,100 tons of gas petroleum. The remainder comprised aviation gasoline, gas oil, light fuel oil, and other products. The largest market for French petroleum products was Switzerland, followed by West Germany, Algeria, and the United Kingdom. Switzerland was the largest market for French gasoline and gas oil, West Germany for fuel oils, and Belgium-Luxembourg for liquified petroleum gas. Jet fuel was the most important export to the United States.

In February 1963 the Government issued 10 decrees which in effect will regulate the import, processing, and distribution of petroleum, petroleum products, and residues from nonfranc areas. The decrees, which are to be effective from September 1, 1965, to September 1, 1975, renew the special permit for petroleum imports granted in 1959 to the following companies: Compagnie Française de Raffinage, Antar Pétroles de l'Atlantique, Union Industrielle des Pétroles (UIP) Esso Standard S.A.F., Mobil Oil Française, Société Shell Française, Société Française de Pétroles B.P., Compagnie des Produits Chimiques et Raffinerie de Berre. These companies are now authorized to continue importing petroleum for an additional 10 years. At the same time a new license was issued to Union Générale des Pétroles (UGP) which was formed in 1960 as the French Government's instrument for refining and marketing Saharan crude oil. The decree establishes for each company quantities of gasoline which it may refine from nonfranc area crude. Gasoline which the French-owned companies may produce from nonfranc crude has been increased from 2,762,301 tons in the present quota to 3,678,690 tons for 1965–75, but the allotments have been left unchanged for foreign-owned companies (2,320,984 tons).

As a result of the large increase in the quantities of gasoline that the UGP–UIP group is licensed to produce from nonfranc crude (870,000 tons for 1965–75 compared with 238,187 tons under the quota prevailing in 1964), the relative share of total imports allocated to all the other companies was reduced. Furthermore, the Government may increase the quantity of crude that one company may import by 15 percent annually without increasing the quantities allowed to others. A decree was issued confirming the right of the Compagnie Française de Raffinage to import enough crude petroleum from nonfranc areas to enable the company to make available for French internal consumption 25 percent of all the refined petroleum products that can be produced for this market by all companies from nonfranc petroleum. Henceforth, every investment by the companies for new plants and equipment must be approved by the Government.

Refining.—During 1963, French refineries treated 46.7 million tons of crude petroleum with a gross output of 44.1 million tons of products and a net output of 42.8 million tons—12 percent more than in 1962. Crude from the franc zones represented 40 percent of the refinery throughput, and refineries operated at 89 percent of capacity as in the previous year. In 1963, fuel oils, excluding domestic fuel oil (a distillate cut), accounted for 33 percent, and domestic fuel oil accounted for 19.5 percent of gross production; other products in percent were gasoline 19.1, gas oil 10.6, bitumen 4.1, as well as propane and butane 3.1.

The two new refineries, both inland, at Reichstett and Herrlisheim in the vicinity of Strasbourg increased total annual capacity to 51.8 million tons, distributed as follows: Lower Seine 18 million tons, Atlantic coast 8.5 million tons, Mediterranean 15.9 million tons, and Alsace 6.5 million tons. The Feyzin refinery, also inland, was to come on stream in 1964. The South European pipeline from Lavera to Karlsruhe and Ingolstadt supplied the two Strasbourg refineries and will also supply the refinery at Feyzin.

Source: Comité Professionnel du Pétrole (Paris). Activité de l'Industrie Petrolière. V. I, 1962, 211 pp.; v. I, 1963, 216 pp.

The 18 refineries which were in operation at the end of 1963 were owned by 9 companies, including the 2 companies that own the Strasbourg refineries. Of the nine companies, Compagnie Française de Raffinage, Compagnie de Raffinage Shell-Berre, Esso Standard S.A.F., and Société Française des Pétroles B.P. were the largest with 24.3, 19.7, 13.7, and 13.3 percent, respectively, of total 1963 installed capacity. The Merkwiller refinery belonging to Antar Pétroles de l'Atlantique and Société Anonyme d'Exploitation Minières Pechelbronn stopped operation in May 1963.

Secondary processing facilities in French refineries included thermal cracking in 10 refineries; reforming (mostly catalytic) in 13 refineries, and vacuum distilling in 10 refineries.

Consumption.[24]—A record 36 million tons of refined petroleum products was marketed during the year. The 18.5-percent expansion in 1963 resulted in part from the severe winter conditions that increased total sales of domestic fuel oil (a distillate cut) from 6,897,400 tons in 1962 to 9,027,300 tons in 1963. With a normal winter, internal demands would have been closer to 35 million tons, or a 17.8-percent increase. Sale of other products also increased compared with 1962 figures—25.5 percent for heavy fuel oil, 8.9 percent for gasoline, 11.9 for gas oil, 6.5 percent for kerosine, 3.9 percent for light fuel oil. The share of industry in total consumption increased at the expense of transportation.

[24] Equivalent to sales to civilian users. The figures do not take into account refineries' own consumption, refinery storage, and transportation losses or change in stocks of consumers and retailers.

Grand total disposal	40.39	47.71

[1] Data presented differ slightly from those given elsewhere in the chapter because of differences in sources.

Sales of domestic fuel oil were distributed as follows: Heating of homes 3,940,900 tons, industrial space heating 3,270,700 tons, agriculture 1,203,100 tons, and others 154,700 tons. Principal customers for heavy fuel oil were: Industry 5,840,700 tons, Electricité de France 1,431,400 tons, French railroads 849,500 tons, domestic space heating 469,000 tons, other 73,100 tons, making a total of 8,663,700 tons. Here the increase was less influenced by the weather than by larger sales to Electricité de France and industry. Increased industrial activity and a shift by industry toward greater use of petroleum products were the reason for larger sales to industry.

The 8.9-percent increase in gasoline consumption was less than the increase in the number of motor vehicles in service: 9,045,600 in 1963 compared with 8,079,100 in 1962. An important factor was a decline in average miles driven because of road congestion. This was especially true in the Paris Basin where gasoline consumption increased 6.1 percent compared with the 8.9 national average. However, sales of high octane gasoline increased.

Digitized by Google

Direct sales of liquified petroleum gas to consumers increased during the year, presumably because of new customers and expanded consumption by existing customers. Gas works also took 122,700 tons, mainly propane.

TABLE 49.—Estimated breakdown of petroleum consumption by end users

(Thousand metric tons and percent)

	1962		1963

The share of various prdoucts in total consumption has changed significantly since 1950 with fuel oil increasing percentagewise and motor gasoline and gas oil decreasing; however, gas oil did not decrease as steeply as motor gasoline.

The Paris area was the largest market for petroleum products with 21.8 percent of the total in 1963.

TABLE 50.—Distribution of petroleum product consumption by product type

(Percent)

	1950	1953	1956	1959	1962	1963

Transportation and Distribution.—In 1963, 91 percent of the 39.9 million tons of crude received in French ports were carried in French tankers. As of December 31, 1963, France had 93 tankers, distributed in size categories on the basis of deadweight tonnage as follows: 2—75,000 or more; 9—50,000 to 74,999; 7—40,000 to 49,999; 33—30,000 to 39,999; 41—15,000 to 29,999; and 1—10,000 to 14,999. Sixty-two have been put into service since 1955. For internal transportation, in 1963 there were 788 barges with a total capacity of 411,153 cubic meters; 14,714,839 tons of oil were carried by river transportation.

Besides the South European crude pipeline from Lavera to Karlsruhe and Ingolstadt in Germany, there is a product pipeline from Le Havre to Paris (Trapel) which transported 3,279,000 tons of products in 1963. The Lavera-Karlsruhe line is 760 kilometers long with 25 million tons annual capacity which will be increased to 30,000,000 tons in 1965. The Le Havre-Paris line consists of 243 kilometers of 10-inch line and 182 kilometers of 12-inch with a total carrying capacity of 4,000,000 tons. Another line (94 kilometers long, 12 inches in diameter) from Parentis to Bec d'Ambès connects the Parentis field to the Esso refinery and extends another 4 kilometers at 16 inches in diameter to Bec d'Ambès. This line has a carrying capacity of 243 cubic meters per hour and transported 1,862,588 tons of crude in 1963.

There were 44,000 gas stations in 1962 with average disposal of 200 cubic meters of products per month. Names of principal companies and approximate number of their stations were as follows: Total [25] 7,000, Azur 6,000, Esso 5,700, Shell 5,600, Antar 4,600, Pétroles B.P. 3,500, Mobil 2,000, Avia 2,000, Petrofina 2,000, UIP 1,800, and others 4,000.

Natural and Manufactured Gas.—In spite of a strike from March 7 to March 21 at the Lacq field, natural gas production increased by 7.5 percent in 1963. Lacq is France's largest natural gasfield and contributed 95.8 percent to the 1963 and 94.4 percent to the 1959–63 output. Recoverable reserves of natural gas as of December 31, 1962, were reported at 160 billion cubic meters.

In 1963, 4,847.6 million cubic meters of natural gas were delivered to the following users: 1,521 million to Gaz de France, 1,309 million for production of electricity, 1,215 million to chemical or parachemical industries, 278 million to lime, glass, and ceramic industries, 222 million to iron and steel and nonferrous metal industries, and 262 million to other industries. The remainder, 40 million cubic meters or 0.8 percent, was used in transportation as motor gasoline condensate. Of total natural gas sales of 4,854.5 million cubic meters in 1963,[26] the Paris region took 26.8 percent, Aquitaine where the gas is produced

[25] Brand name.
[26] Sales figures are slightly different from deliveries.

Digitized by Google

took 29.8 percent, Midi-Pyrénées took 14.23 percent and Rhône-Alps took 11.81 percent.

As of January 1, 1963, 4,250 kilometers of pipeline transported Lacq natural gas to consumers. In southwest France natural gas is marketed by Société National des Gaz du Sud Ouest and in other areas by Compagnie Française du Méthane.

Exports and loss	2.2	2.5	2.3	3.4
Total	63.0	76.6	85.1	92.1

[1] 1,000 kilocalories is equivalent to 0.15 standard coal equivalent volume of gas in cubic meters of 4,200 kilocalories per cubic meter and it can be obtained by dividing number of kilocalories by 4,200.
[2] Detail does not add to total because of rounding.

Exploitation of the St. Marcet and Lacq gasfields has made a significant change in the structure of the gas industry of France which had previously been almost entirely dependent on coal distillation. Gaz de France has continued to produce gas from coal mainly from its coking plants in the Paris area and in the neighborhood of Strasbourg and Raven.

In 1962, natural gas constituted 31 percent of all gas produced compared with 14 percent in 1959. Excluding blast-furnace gas, of which production has been fairly stable since 1959 and which is almost wholly used for underfiring coke ovens and for power production in steel plants, the share of natural gas in the total gas production increased to 46 percent in 1962 at the expense of manufactured gas. The share of gasworks gas dropped from about 17 percent in 1959 to 5.8 percent in 1962, and the share of coke oven gas dropped from 39 percent in 1954 to 26 percent in 1962. Some 450 gasworks were closed during 1947–62. In absolute units there actually has been a slight increase in coke oven gas production. In view of the large increase in refinery

Digitized by Google

capacity, the volume of refinery gas has increased by almost two-thirds, but its share of total gas production other than blast-furnace gas increased by only 1 percent.

Of the several notable byproducts of French gas production and processing, sulfur is by far the most significant.

Natural gas from the Sahara was expected to be added to the French supply starting in 1965, when the Arzew plant is scheduled to supply 500 million cubic meters of methane per year to Gaz de France. The gas, as liquid methane, will be carried by tankers to Le Havre where it will be re-gasified for delivery to the lower Seine and Paris area. Building of a methane tanker in France was started in 1963. It will have a capacity for 25,500 cubic meters of liquefied gas and a 11,500-ton cargo.

The Government's participation in refining was through 60-percent ownership of Union Industrielle des Pétroles and 100 percent ownership of Union Générale des Pétroles. Compagnie Française de Pétrole, which is a member of the Iraq Petroleum Co. group, Abu Dhabi Marine Area, Ltd. and Dubai Marine Area, Ltd., is also 35 percent Government owned. This company, through its subsidiary, Compagnie Française de Raffinage, is the largest refiner of petroleum in France.

The Mineral Industry of East Germany

By Roman V. Sondermayer [1] and Bernadette C. Michalski [2]

EAST GERMANY, a fairly industrialized area with a well-developed metallurgical base, produced many mineral products in 1963 from domestic and imported raw materials. The emphasis given to the mineral industry is shown by the fact that 1.5 billion East German marks [3] of new investments were made during the year. However, in relationship to world mineral output only brown coal and potash were of considerable significance. The metallurgical industry has been expanded much beyond the domestic raw material base and this has resulted in heavy import demands. The principal mineral products with production expressed in percentages of 1962 world totals were approximately as follows: Fuel briquets, 51 percent; brown coal coke, 21 percent; potash, 17 percent; coal, 9 percent; fluorspar, 3 percent; salt, 2 percent; silver, 2 percent; aluminum, barite, cement, copper, gypsum, iron ore, lead, pig iron, pyrites, steel ingots, tin, and zinc from 0.3 percent to 1.5 percent.

During 1963, the major events in the mineral industry were concentrated in the production of brown coal, development of facilities for production of chemicals from brown coal, continued construction of the Brandenburg steel complex, and completion of the Druzba pipeline. The refinery at Schwedt, at the western end of the Druzba pipeline, was under construction in 1963 and was expected to be operational in 1964. The coke quenching installation in Lauschammer, scheduled for production in 1964, should bring about an increase in the quality and quantity of high temperature brown coal coke.

The overall activity of the mineral economy was sluggish in 1963. Construction and investments failed to achieve planned goals partly because of low labor productivity. During the winter of 1963, the regime introduced new measures to boost the economy. According to official reports, one of the measures introduced was an effort to encourage labor incentive by scaling labor pay to the profit made by the enterprise. This approach to stimulating productivity was completely new in East Germany.

PRODUCTION

The most advanced segments of the mineral economy were brown coal mining with its related industries, and potash production and

processing facilities. With the exception of alumina and copper ore, output statistics on nonferrous metals were, as usual, not published. However, it is known that some lead, zinc, tin, nickel, and uranium also were produced.

Output of iron ore in 1963 made no appreciable gain over the previous year, and only nominal increases were reported in production of pig iron and steel. Output of pig iron rose by only 1 percent and that of steel by 2 percent.

Enough major nonmetallics were extracted for domestic consumption. The potash industry maintained its leading position among the nonmetallics, although the cement industry also had a successful year.

The major domestic source of primary energy was coal; brown coal and related industries were the dominant elements. Petroleum requirements were covered by imports and by the production of synthetic oils from brown coal. Only very minor quantities of crude petroleum and natural gas were produced.

TRADE

In spite of increased production in 1963, East Germany remained dependent upon imports to provide a major part of its supplies of mineral raw materials and a significant share of its processed mineral product requirements. Official trade statistics[4] are incomplete because they omit listings of a number of commodities recorded as exported to or imported from other countries in the foreign trade records of those countries (notably the U.S.S.R. and Poland). These statistics also do not include data on the geographic distribution of individual commodities in trade. Nevertheless, the basic geographic and commodity patterns of East Germany's international trade in minerals and mineral products is evident. Throughout 1963 mineral trade was characterized by the import of raw materials and the export of semifinished and finished products.

Officially reported mineral exports in 1962 were confined to nonmetals (the foremost of which were cement and potash) and to mineral fuels (chiefly brown coal briquets). However, import statistics of the Soviet Union and Poland give East Germany as the source of iron and steel semimanufactures and a number of nonmetals and petroleum products not specified in East German trade statistics.

TABLE 2.—Export of selected mineral commodities

(Metric tons unless otherwise specified)

Commodity [1]	1961	1962
Nonmetals:		
Cement—thousand tons	239,100	181,100
Gypsum, burned	37,802	35,819
Potassic materials (K_2O equivalent)—thousand tons	1,047	1,147
Sulfur	33,552	41,719
Mineral fuels:		
Coal:		
Bituminous	200	600
Brown coal briquets—thousand tons	6,205	6,602
Brown coal coke—do	118	114
Petroleum:		
Refined products:		
Gasoline	370,303	387,982
Diesel oil	376,258	369,904
Natural and manufactured gas—million cubic feet	185	207

[1] Official import statistics of the Soviet Union and Poland indicate that East Germany also exported quantities of the following mineral commodities: Steel semimanufactures, fluorspar, graphite, cryolite, kaolin, mica, ashpalt, paraffin, other petroleum products (in addition to gasoline and diesel oil), and carbon black.

[4] Statistisches Jahrbuch Der Deutschen Demokratischen Republik 1963 (Statistical Yearbook of the German Democratic Republic 1963). Leipzig, 1963, pp. 361–366.

Digitized by Google

Import statistics also do not list all the mineral commodities listed in export data for the U.S.S.R. and other countries. However, these data, although incomplete from the viewpoint of the range of commodities covered, show appreciable imports of several major items.

Through its integration into the joint economic efforts of the Soviet Ekonomicheskoy Vzayimopomoshchi (S.E.V.),[5] East Germany has become the leading importer of minerals and mineral products from the U.S.S.R. Moreover, the U.S.S.R. ranks as the principal supplier of these commodities. Significant quantities of aluminum, copper, lead, pig iron, pipes and other rolled steel were imported from the U.S.S.R. in 1963. Crude and refined petroleum were also important among imports from the U.S.S.R.

TABLE 3.—Officially recorded imports of metals and minerals[1]

(Metric tons unless otherwise specified)

COMMODITY REVIEW

METALS

Aluminum.—Two aluminum plants were operating in East Germany during 1963. The plant at Bitterfeld produced some 35,000 tons of aluminum from imported alumina during the year. The plant at Lauta turned out alumina and aluminum from imported Hungarian and Yugoslavian bauxites. The aluminum capacity of the Lauta plant was about 20,000 tons annually. Both plants were modernized during 1963.

Copper.—Copper was mined in Mansfeld near Halle, and smelted at the Wilhelm Pick Kombinat, at Eisleben. The Kombinat has a capacity of 30,000 tons of copper annually. In addition to copper, the plant produced soft lead, pure selenium, cadmium, silver, gold, platinum and vanadium in undisclosed quantities.

Iron and Steel.—Large postwar investments were made to develop the iron and steel industry with the assistance of the Soviet Union.

Digitized by Google

Iron ore mined in East Germany has been low grade and was mainly produced by mining enterprises around the "Thuringen Waldes" near Schmiedefeld and Badeleban. Output has been far below demand, and efforts were made in 1963 to expand iron ore production through modernization of facilities. Because of unfavorable geologic conditions and high consumption of iron and steel products East Germany is likely to continue to depend largely upon foreign iron ore.

During 1963 the three most significant iron and steel plants in operation were: The West Iron Smelting Works (VEB Eisenhutten Werk West), the Brandenburg Steel Works and Rolling Mills (VEB Stahl und Walz Werke Brandenburg), East Iron Smelting Combine (VEB Eisenhuttenkombinat Ost-EKO).

The postwar West plant uses domestic siliceous ores and coke produced from brown coal. According to available information, the 10 low-shaft furnaces of the plant have a reported combined output of around 250,000 metric tons of pig iron.

Facilities at the modern Brandenburg plant included 12 150-ton open-hearth furnaces and rolling mills capable of producing blooms and slabs up to 9 tons in size. Work was underway to increase the annual capacity to 3 million tons by 1964. The plant employed about 6,500 workers in 1963.

The East Iron and Steel Combine is an integrated plant, based upon Soviet iron ore and on coke imported from other East European countries. The sintering and blast furnace units have rated annual capacities of approximately 1 million tons. Steelmaking facilities include six 50-ton open-hearth furnaces, four 15-ton basic Bessemer converters, and several electric furnaces. A continuous strip mill is scheduled to increase the capacity for sheet output fivefold.

Another 15 small plants scattered around the country produced about 3 million tons of steel during 1963.

Other Metals.—Small quantities of other metals were produced in 1963. The old Freiberg Electrolytic Lead Works was expanded. The Sankt-Egidien Nickel Works was near completion, but details on production were withheld. Uranium was produced in Erzgebirge.

NONMETALS

Cement.—The cement industry with its 13 plants and output of 5.5 million tons covered domestic requirement for 1963.

Potash.—The area's principal nonmetallic product was potash. More than half of the total production came from Erfurt where reserves are extensive. Half of the potash output was exported.

Because of the drive to increase agricultural production in the communist area, potash mines were being modernized and many new facilities were under construction.

Other Nonmetals.—East Germany produced adequate quantities of salt, clays, dolomite, and other minerals for domestic consumption.

MINERAL FUELS

Coal.—Extensive reserves of brown coal and large-scale extraction have made this segment of the mineral industry the most important

Digitized by Google

source of energy. Brown coal is also the foundation for the chemical industry.

Large deposits of brown coal near the surface permit open pit mining with use of heavy equipment for mass production. The latest trend in the development of brown coal deposits has been to build facilities near the deposits to convert brown coal into gas, electric energy, and chemicals without costly haulage of the raw material. Methods have been devised for converting brown coal to coke for use in smelting domestic iron ores.

Four brown coal hydrogenation plants producing liquid fuels were in operation during 1963. Production of synthetic fuels may decline, with the Schwedt oil refinery covering more of the overall liquid fuel demand.

Petroleum.—Little crude petroleum was extracted in the area during 1963. The regime was trying to increase supply by organizing large oil and gas exploration programs with the assistance of Soviet specialists and equipment. So far, no significant discoveries of oil or natural gas have been announced and the area continued to be heavily dependent upon imported crude petroleum to cover domestic needs.

A refinery processing domestic crude oil at Leutzkendorf, was reported to have an annual capacity of 800,000 tons. The Schwedt refinery, terminal of the Druzba pipeline supplying crude oil from the U.S.S.R., was near completion in 1963.

The Mineral Industry of Federal Republic of Germany

By L. Nahai[1]

THE FEDERAL REPUBLIC OF GERMANY (West Germany) ranked 3d in world production of pig iron and crude steel, 6th in smelter copper and lead and 10th in cadmium in 1963. In nonmetallics it was second in production of barite, feldspar, and potash, fourth in cement, and fifth in salt. The country was the leading producer of crude petroleum and bituminous coal in Western Europe and ranked fourth as a world producer of bituminous coal. As a large consumer of minerals and metals, it also continued to play an important role with respect to other commodities.

The gross national product of West Germany increased by 6 percent in 1963. However value of mineral production may not have attained that level of growth; the slight drop in production of iron and steel and some of the nonferrous metals may not have been sufficiently compensated by the increased production of petroleum and building raw materials.

The country was partially dependent on foreign sources of some raw metals; domestic production supplied only part of the iron, lead, and zinc ores consumed by the metallurgical industry. Other metals and ores and a number of industrial minerals including asbestos, magnesite, mica, phosphate, and native sulfur were not produced at all. However, the country was self-sufficient in pit and quarry products used in the building, cement, and ceramic industries. Imports were mainly in the form of ores, concentrates, and crude metals, which were treated by the Federal Republic's diversified metallurgical and processing industry to produce an extensive range of metal and mineral products.

The gross national product of West Germany at current prices in 1963 totaled approximately $94,000 million. Available published data in 1962 do not report the contribution of the mineral industry as a whole to the gross domestic or national product. In 1961, the latest year for which data are available, the contribution of mining to the gross domestic product of US$77,840 million (in current prices) was US$2,200 million, or 2.82 percent. However, this figure is only part of the total contribution because it excludes the value output of the important pit and quarry products and of the petroleum and smelting industries. A more useful measure of the role of the mineral industry is the total sales, for which rather detailed information is availa-

[1] West Europe specialist, Division of International Activities.

Digitized by Google

ble. For the types of operations tabulated, the sales were about 16 percent of the total of US$76,400 million for all the industry. These activities also employed over 1 million persons, 38 percent of whom were engaged in coal mining.

TABLE 1.—Employment and total sales in the mineral industry in 1963

Industry	Employment [1] (workers and staff)	Total sales (millions)		
		Domestic	Foreign	Total
Mines:				
Coal	411,453	US$1,634	US$503	US$2,137

[1] December 1963.

PRODUCTION

West German industrial production in 1963 increased by 3.6 percent. Some sections of the mineral industry increased more, but the important iron and steel industry and the three principal primary nonferrous metals declined, although output of secondary lead and zinc increased significantly. Aluminum continued its growth both in ingot metal and semimanufactures. While increased competition in world markets has not permitted a marked increase in potash production, growth in the chemical industry, which in 1963 had a production almost 10 points above that of 1962, has indirectly favored salt mining. Similarly, high levels of construction and public works stimulated the output of pit and quarry products. Coal production has varied little in the last 5 years, but crude and natural gas production and refinery throughput have increased substantially.

Peat:					
Agricultural use thousand tons	845	812	523	612	[1] 770
Fuel do	882	790	753	826	[1] 830
Natural gas million cubic feet	14,466	16,709	17,960	23,007	34,148
Petroleum:					
Crude thousand tons	5,103	5,530	6,204	6,776	7,383
Petroleum products:					
Fuel oil do	8,580	13,341	17,407	19,312	23,046
Motor gasoline do	4,474	5,383	6,539	7,262	8,176
Diesel oil do	4,430	4,842	5,573	6,155	7,246
Liquefied gas do	604	770	846	853	1,102
Turbofuel do	219	208	366	572	558
Kerosine do	46	52	50	58	81
Lubricants do	429	481	512	564	554
Bitumen do	1,078	1,160	1,387	1,804	2,304
Total, including other products [9]	21,289	28,021	34,969	39,304	46,439

[1] Estimate.
[2] Data not available.
[3] Revised figure; differs from that given in commodity chapter, volume 1.
[4] Including production of refinery lead by battery makers.
[5] Includes zinc recovered from imported ores.
[6] Includes cementlike mortar.
[7] Exclusive of Saar.
[8] Excludes output of small producers of 763,000 tons in 1962 and about the same in 1963.
[9] Includes refineries' own consumption, not detailed above.

TRADE

Imports and exports of tabulated minerals and metals in 1963 contributed 50 and 31 percent of total imports and exports, respectively. Coal and coke ranked first in export value with 16.7 percent of all exports from the Republic, followed by iron and steel (including scrap), with 7.3 percent. Petroleum and petroleum products con-

Digitized by Google

tributed the largest import group in value, accounting for 64 percent of mineral imports and 32 percent of all imports.

In 1963, 34 percent of all exports from West Germany went to the six countries of the European Economic Community (EEC); 62 percent went to the EEC countries and the European Free Trade Association (EFTA) countries combined. The EFTA includes Austria, Great Britain, Denmark, Norway, Portugal, Sweden, and Switzerland. The import figures were 32 percent from the EEC countries and 51 percent from the EEC and EFTA countries combined. For the minerals and metals tabulated, West Germany's exports to the Common Market in 1962 (approximately US$1,216 million) were 50 percent of the US$2,430 million exports to all destinations; for the same commodities, 27 percent of the value of imports (estimated at US$2,940 million) was from the EEC countries. In view of large imports of crude petroleum and other raw material from sources other than EEC, these countries are less important as sources of imports than as destinations for Germany's exports.

TABLE 3.—Mineral and metal trade in 1963

Commodity	Imports		Exports	
	Quantity (thousand metric tons)	Value (millions)	Quantity (thousand metric tons)	Value (millions)
Iron ore including pyrite cinder	28,916	US$282	547	US$2
Iron and steel scrap	638	21	1,299	42
Pig iron and ferroalloys	690	57	907	52
Steel	4,252	574	7,311	1,063
Nonferrous metal ores	3,192	115	112	10

Scrap	885	2,068	3,231	Italy 2,392; France 517; Belgium-Luxembourg 276; total EEC 3,216.
Dust and powder	1,940	2,034	1,742	Czechoslovakia 677; Austria 210; Switzerland 182; Italy 161; total EEC 374.
Semifabricated	5,933	4,699	5,654	Denmark 720; Netherlands 595; Turkey 342; Sweden 336; France 329; total EEC 992.
Slab	31,701	25,392	29,870	United States 9,174; Switzerland 2,576; Philippines 2,509; Sweden 2,255; France 2,018; Belgium-Luxembourg 1,845; Netherlands 1,823; total EEC 7,057.
Zirconium	2	2	7	Sweden 6.
Alkali earth and rare earth metals.	2,710	2,895	3,073	(3).
Other nonferrous metals	13	11	9	Italy 3; Rumania 3; United States 2 total EEC 3.
Other ores and concentrates	18,257	2,113	10,292	France 10,216; total EEC 10,237.
Nonmetals:				
Asbestos	928	370	298	Austria 134; Switzerland 57; total EEC 43.
Barite and witherite	123,894	99,798	103,997	France 57,689; Belgium-Luxembourg 16,174; Netherlands 13,609: total EEC 87,513.
Cement, portland and other	972,437	833,704	783,603	Netherlands 421,241; France 228,090; total EEC 649,748. EEC 87,513.
Chalk	476	421	776	Denmark 469; total EEC 77.
Clay:				
Kaolin	33,834	38,399	52,302	Italy 16,681; Switzerland 7,689; Finland 6,282; Netherlands 5,571; France 5,511; total EEC 30,731.
Refractory	367,088	346,404	366,379	Netherlands 82,323; Italy 74,979; Belgium-Luxembourg 62,907; France 52,559; total EEC 272,770.
Other	474,496	467,795	418,192	Netherlands 209,855; France 67,963; Belgium-Luxembourg 62,863; Italy 40,806; total EEC 381,487.
Crushed rock and gravel. thousand tons	4,601	4,411	6,006	Netherlands 3,801; Belgium-Luxembourg 1,265; Switzerland 877; total EEC 5,080.
Diamonds:				
Industrial. thousand dollars	4,396	609	678	Netherlands 213; United Kingdom 116; Belgium-Luxembourg 114; total EEC 348.
Powder ---do	47	45	88	Netherlands 27; France 16; Italy 16; total EEC 70.

TABLE 4.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963 [1]
Diatomaceous earth	4,018	3,807	3,639	EEC 1,503; Belgium-Luxembourg 576; Netherlands 415; Switzerland 371; Italy 368; Sweden 309.
Dolomite	70,775	84,881	57,506	Netherlands 36,370; Belgium-Luxembourg 7,332; France 6,621; total EEC 50,423.
Earth pigments	3,306	2,909	2,556	EEC 1,236; Switzerland 484; Belgium-Luxembourg 434; Sweden 359; Netherlands 335; France 324.
Feldspar, leucite, nepheline, nepheline syenite.	34,904	25,658	11,948	Netherlands 3,916; Belgium-Luxembourg 2,748; Italy 2,748; total EEC 11,383.
Fertilizer raw materials:				
Animal and plant origin	125	1,980	4,665	Netherlands 4,598; total EEC 4,607.
Rock phosphate	30,163	33,543	36,225	Austria 34,405; Switzerland 1,750.
Crude potash	87,356	84,355	73,188	Netherlands 25,479; Belgium-Luxembourg 24,115; United Kingdom 23,059; total EEC 49,836.
Potassium chloride and sulfate up to 52 percent K_2O, potassium-magnesium sulfate up to 30 percent K_2O.	thousand tons 1,589	1,281	1,458	United Kingdom 182; United States 181; Netherlands 144; Denmark 135; total EEC 293.
Fluorspar	34,904	14,335	11,598	Austria 6,344; Netherlands 1,663; Switzerland 1,475; total EEC 2,173.
Graphite	5,430	6,635	4,145	Italy 1,432; United States 1,310; United Kingdom 458; Hungary 309; total EEC 2,030.
Gypsum	178,799	186,961	190,475	Netherlands 95,635; Belgium-Luxembourg 27,123; Sweden 18,783; total EEC 137,756.
Lime	299,520	282,642	291,840	Netherlands 233,797; Switzerland 20,955; Belgium-Luxembourg 18,380; France 14,300; total EEC 266,496.
Limestone	40,241	26,507	36,998	Netherlands 26,865; total EEC 31,159.
Magnesite, crude, sintered and calcined.	4,201	2,524	3,920	Netherlands 1,466; France 1,349; total EEC 3,381.
Mica	323	429	486	Switzerland 244; Sweden 76; Austria 63.
Pumice, emery, other natural abrasives.	692,038	633,398	705,835	Netherlands 477,525; Belgium-Luxembourg 209,696; total EEC 700,911.
Pyrite	600	1	11	[2].
Quartz and quartzite	43,350	45,098	43,247	Italy 13,202; Austria 10,690; Switzerland 5,868; Belgium-Luxembourg 3,617; total EEC 22,118.
Salt	699,865	792,737	890,298	Belgium-Luxembourg 425,317; Sweden 179,480; total EEC 467,988.
Sand	827,275	924,513	1,125,345	Netherlands 678,886; Switzerland 190,815; total EEC 846,029.
Slate	25,514	20,228	40,404	Netherlands 28,757; Sweden 5,837.
Soapstone and talc	1,155	1,058	1,206	Sweden 329; Switzerland 251; Denmark 186; total EEC 30,682.
Stone:				
Marble and other dressed limestone.	3,013	8,530	10,981	Belgium-Luxembourg 8,577; Netherlands 1,227; total EEC 9,882.
Other stones	271,373	262,780	307,489	Netherlands 297,178; France 4,304; Belgium-Luxembourg 4,234; total EEC 306,238.
Flint and tar macadam	26,424	13,869	16,791	Netherlands 12,937; total EEC 16,711.
Sulfur	16,358	21,704	11,725	United Arab Republic (Egypt) 6,673; Denmark 3,071; total EEC 1,208.
Other nonmetals	220,351	265,001	296,766	Netherlands 112,893; United States 31,992; Austria 26,888; total EEC 159,252.
Slags and ashes:				
Slags, ashes, other rejects	thousand tons 1,256	1,187	1,262	Netherlands 793; France 393; total EEC 1,248.
Metalliferous ashes and rejects.	41,925	61,210	58,640	Belgium-Luxembourg 27,647; Netherlands 17,109; United Kingdom 4,414; total EEC 48,361.
Other slags and ashes	226,403	225,624	266,962	Netherlands 213,462; France 43,433; Switzerland 9,401; total EEC 257,186.
Thomas slag	363,609	366,243	408,219	France 311,780; Austria 33,820; Chile 16,290; Netherlands 15,291; total EEC 328,909.

TABLE 4.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963 [1]
Mineral fuels:				
Hard coal.....thousand tons..	16,934	17,909	16,352	France 6,164; Netherlands 3,992; Belgium-Lumxebourg 2,809; Italy 1,142; Austria 949; Switzerland 800: total EEC 14,107.
Lignite (brown coal).....	248,964	220,121	196,361	Mainly to the Netherlands.
Lignite bri- thousand tons.. quets.	1,457	1,448	1,514	France 475; Belgium-Luxemourg 245; Netherlands 225; Switzerland 206; Austria 202; total EEC 1,107.
Hard coal coke.....do....	10,920	10,289	12,046	France 4,547; Belgium-Luxembourg 3,360; Sweden 895; Denmark 761; Switzerland 515; total EEC 8,800.
Lignite semicoke.....	24,602	25,266	26,619	Denmark 20,853; Switzerland 5,686.
Peat and other, including their semicokes.	167,747	158,503	151,298	Netherlands 62,119; United States 31,745; Switzerland 23,474; total EEC 83,903.
Petroleum products:				
Gasoline.....thousand 42-gallon barrels.	9,976	9,997	10,589	Switzerland 3,885; United Kingdom 2,270; Sweden 1,816; Denmark 898.
Kerosine and jet do.... fuel.	142	1,711	1,197	Netherlands 658; Denmark 256; United Kingdom 184.
Distillate fuel oil.....do....	5,580	5,841	8,555	Switzerland 5,072; Denmark 1,527; Netherlands 918.
Residual fuel oil.....do....	14,785	8,535	12,809	Netherlands 4,897; Switzerland 3,897; United Kingdom 1,396; Belgium-Luxembourg 1,148.
Lubricating oil.....do....	569	525	625	Netherlands 180; Austria 80; Belgium-Luxembourg 78; United Kingdom 78.
Liquefied petroleum do.... gas.	2,673	2,640	2,575	Belgium-Luxembourg 947; Denmark 717; Netherlands 672.
Asphalt.....do....	415	664	951	Switzerland 348; Denmark 304; Netherlands 238.
Other.....do....	911	1,053	1,290	France 308; Switzerland 243; Cameroon 151; Sweden 75.
Total.....do....	35,051	30,966	38,591	
Bunkers.....do....	17,323	8,117	20,802	

[1] For most items, the total export to the European Economic Community (EEC) is indicated; part or all of this EEC total is duplicated in the listing of individual countries wherever Belgium, France, Italy, Luxembourg, or the Netherlands appears as a separate entry.

TABLE 5.—Imports of metals and minerals

(Metric tons, unless otherwise specified)

Commodity	1961	1962	1963	Principal sources, 1963 [1]
Metals:				
Aluminum:				
Bauxite	1,563,288	1,391,418	1,508,017	Yugoslavia 736,602; Greece 343,461; France 147,904; Hungary 90,926; Indonesia 51,177; total EEC 151,428.
Alumina-anhydrous	27,741	34,618	49,665	Mainly from Guinea.
Ingots	138,716	117,989	120,671	Norway 30,428; Canada 26,357; United States 20,034; Switzerland 11,318; France 4,732; total EEC 5,082.
Scrap	45,913	41,936	43,934	United States 19,546; Netherlands 6,150; France 5,028; Austria 2,593; Belgium-Luxembourg 2,352; total EEC 13,534.
Semifabricated	11,801	12,623	18,440	Belgium-Luxembourg 7,635; Nethe lands 2,374; France 1,507; United States 805; Switzerland 504; total EEC 11898.
Antimony:				
Ore	2,209	1,648	2,165	Turkey 1,477; mainland China 284; Thailand 265.
Metal	3,592	3,602	4,782	Mainland China 2,649; U.S.S.R. 932; Czechoslovakia 921; Hungary 162.
Bismuth	236	280	254	Netherlands 80; Belgium-Luxembourg 53; United Kingdom 42; mainland China 32; total EEC 134.
Cadmium	810	918	1,003	Belgium-Luxembourg 331; U.S.S.R. 235; United States 150; Netherlands 101; total EEC 435.
Chromium:				
Chromite	324,159	228,122	174,496	Republic of South Africa 71,439 U.S.S.R. 57,929; Turkey 28,049 Iran 12,546.
Metal	49	39	75	France 52; United Kingdom 18.
Cobalt	770	580	466	Belgium-Luxembourg 280; United States 60; France 39; total EEC 345.
Columbium and titanium	230	322	388	United States 329; Japan 26.
Copper:				
Ores and concentrates	130,022	133,624	158,545	Cyprus 90,512; Chile 36,492; Canada 8,394; Morocco 8,145; Norway 7,576; Algeria 3,279.
Matte	8,107	7,453	2,358	Norway 1,125; Austria 510; Burma 331.
Scrap, including alloy scrap	34,133	27,032	42,834	Netherlands 11,158; France 5,494; Switzerland 5,113; Denmark 4,602; total EEC 19,403.
Ingots for refining	122,070	101,019	122,100	Rhodesia 46,557; Chile 32,211; Peru 18,042; Republic of South Africa 7,066.
Refined, not alloyed	346,801	300,814	255,211	Chile 77,157; United States 57,140; Belgium-Luxembourg 49,436; Rhodesia 36,073; total EEC 51,408.
Refined, alloyed	31,046	36,670	38,979	United Kingdom 12,307; France 6,113; Argentina 5,731; Netherlands 5,211; total EEC 12,815.
Master alloys	1,007	547	476	United Kingdom 162; Switzerland 149.
Semifabricated	27,642	20,105	26,496	Belgium-Luxembourg 15,116; Netherlands 2,983; Sweden 2,500; total EEC 20,224.
Gold:				
Unwrought—troy ounces	2,637,936	3,031,782	2,174,194	U.S.S.R. 1,286,865; Switzerland 422,654; United Kingdom 209,623.
Semifabricated—do	9,998	9,356	12,892	United States 8,584; Austria 3,665.
Scrap and ashes [2]	30	17	21	Austria 7; United States 4; Italy 2; Sweden 1; Denmark 1; total EEC 3.

TABLE 5.—Imports of metals and minerals—Continued

(Metric tons, unless otherwise specified)

Commodity	1961	1962	1963	Principal sources, 1963 [1]
Metals—Continued				
Iron and steel:				
Ore.....thousand tons..	32,628	29,069	27,000	Sweden 7,967; France 6,802; Brazil 2,587; Liberia 1,655; total EEC 6,810.
Pyrite cinder.....do....	2,481	1,864	1,915	Spain 555; France 221; Italy 197; Belgium-Luxembourg 197; Sweden 181; total EEC 675.
Scrap.....	941,304	621,220	638,277	Belgium-Luxembourg 209,039; Netherlands 207,571; United Kingdom 102,409; total EEC 450,455.
Pig iron and spiegeleisen.....thousand tons..	340	611	479	Spain 94; Finland 68; U.S.S.R. 64; Republic of South Africa 56; United Kingdom 45; total EEC 84.
High-carbon ferro-manganese.....do....	78	71	71	France 37; Norway 12; Republic of South Africa 10; total EEC 40.
Other ferroalloys....do....	169	138	140	Norway 66; France 21; Yugoslavia 12; Switzerland 10; total EEC 25.
Ingots, blooms, billets.....do....	285	241	223	Belgium-Luxembourg 166; France 24; United Kingdom 10; Austria 6; Sweden 4; total EEC 192.
Rolled steel.....do....	3,168	4,032	4,020	Belgium-Luxembourg 1,468; France 1,227; Austria 465; Netherlands 302; total EEC 3,048.
Pipes and other.....	80	104	123	[4].
Lead:				
Ores and concentrates.....	146,711	144,748	109,198	Sweden 31,418; Peru 30,525; Canada 7,737; Morocco 6,318; Greece 5,865.
Scrap.....	1,264	1,285	1,246	Belgium-Luxembourg 616; Netherlands 241; total EEC 987.
Pig and refined.....	76,539	99,962	100,563	United Kingdom 28,561; Austria 18,327; France 13,902; Peru 11,120; Belgium-Luxembourg 8,791; Netherlands 5,738; Mexico 5,358; total EEC 28,474.
Semifabricated.....	478	1,233	1,843	Belgium-Luxembourg 878; France 420; Yugoslavia 370; total EEC 993.
Magnesium:				
Scrap.....	124	131	78	Sweden 31; Netherlands 26; Austria 10; total EEC 26.
Ingots.....	26,274	29,883	30,940	Norway 15,147; United States 10,522; Italy 3,001.
Semifabricated.....	95	126	159	Austria 89; United States 46; United Kingdom 23.
Manganese:				
Ores and concentrates.....	553,898	518,314	730,684	Republic of South Africa 237,378; India 102,666; Gabon 73,272; U.S.S.R. 71,752.
Metal.....	1,603	1,664	1,476	Japan 764; Republic of South Africa 441; United States 111; France 84.
Mercury.....76-pound flasks..	27,093	23,554	16,331	Italy 11,197; Spain 2,495; mainland China 1,218; Yugoslavia 435; Mexico 319.
Molybdenum, including scrap..	122	89	65	Netherlands 23; Austria 21; United States 17; total EEC 25.
Nickel:				
Ores and concentrates.....	16	20	693	All from Greece.
Matte.....	1,225	488	1,260	Greece 569; Canada 496.
Scrap.....	3,463	3,820	4,325	United States 1,682; Netherlands 688; France 590; United Kingdom 550; total EEC 1,281.
Ingots.....	19,587	18,909	19,217	United Kingdom 6,363; Norway 4,976; Canada 4,780; United States 1,785.
Semifabricated.....	1,014	868	516	United Kingdom 148; United States 106; Switzerland 85; France 20; total EEC 90.
Anodes.....	450	354	392	France 129; Switzerland 78; Netherlands 55; total EEC 201.
Platinum, unwrought and semifabricated.....troy ounces..	115,740	106,420	325,349	U.S.S.R. 163,904; United Kingdom 100,149;
Palladium.....troy ounces..	102,880	108,670		Switzerland 21,251; total EEC 24,338.
Selenium.....	125	73	[3] 110	[4].
Silicon.....	13,675	12,442	12,704	Italy 3,300; France 2,925; Sweden 2,550; Switzerland 2,176; total EEC 6,230.

TABLE 5.—Imports of metals and minerals—Continued

(Metric tons, unless otherwise specified)

Commodity	1961	1962	1963	Principal sources, 1963 [1]
Metals—Continued				
Silver:				
Ores and concentrates, including platinum.	2,811	3,457	2,402	All from Peru.
Scrap and ashes, including platinum.	221	202	257	Switzerland 68; Austria 43; Norway 40; Sweden 33; Netherlands 31; total EEC 47.
Metal, thousand troy ounces.	44,907	40,975	41,631	Mexico 17,887; Peru 4,897; Belgium-Luxembourg 4,824; total EEC 6,220.
Tantalum, wrought and unwrought.	5	6	3	France 2.
Tellurium	10	10	[2] 3	(4).
Tin:				
Ores and concentrates	6,386	8,105	8,499	All from Bolivia.
Scrap	410	229	364	Netherlands 231; Switzerland 33; total EEC 249.
Ingots	28,361	12,278	11,783	Malaya 4,635; Netherlands 3,087; mainland China 1,006; Belgium-Luxembourg 998; total EEC 4,088.
Semifabricated	12	8	21	Netherlands 3; Switzerland 3.
Titanium, columbium, vanadium, molybdenum, zircon ores and concentrates.	400,209	311,201	319,387	Norway 201,016; Canada 66,189; Australia 34,360; United States 5,705.
Tungsten:				
Ores and concentrates	5,324	4,756	3,975	U.S.S.R. 1,720; Bolivia 631; Argentina 627.
Metal, wrought and unwrought.	164	124	80	France 32; Switzerland 22.
Uranium ores and concentrates	61	23	26	Canada 6; total EEC 40.
Uranium and thorium alloys		28		
Zinc:				
Ores and concentrates	138,433	133,604	124,648	Sweden 40,993; Finland 13,966; Peru 12,180.
Scrap	416	865	792	Netherlands 315; Belgium-Luxembourg 231; Spain 77; total EEC 546.
Dust and powder	1,200	2,303	3,822	Belgium-Luxembourg 2,381; Yugoslavia 555; total EEC 2,399.
Slab	141,579	128,611	136,109	Belgium-Luxembourg 44,144; Netherlands 14,322; Canada 13,217; Norway 9,768; Austria 9,274; total EEC 65,519.
Semifabricated	8,379	10,022	11,210	Belgium-Luxembourg 4,421; Yugoslavia 4,181; France 2,180; total EEC 6,618.
Zirconium, crude and semifabricated.	13	13	13	United States 9; United Kingdom 2; total EEC 1.
Alkali earth and rare earth metals.	14	457	1,612	France 1,492; United Kingdom 110; total EEC 1,492.

COMMODITY REVIEW

METALS

Iron and Ferroalloy Ores.—The decline in iron ore production and shipment, which started in 1962, became steeper in 1963, This decline

Digitized by Google

has resulted from changes in the West German iron ore supply situation.[2] Raw material costs reportedly constituted 80 percent of the cost of production of pig iron. To improve its competitive position, the West German steel industry, particularly in the Ruhr, has increasingly used high-grade imported ore, which in terms of metal content has been cheaper than domestic ore. In 1962 average iron content of imported ore in the Ruhr was 58.2 percent, compared to the average grade of West German mine ore in 1963 which was approximately 27 percent.

TABLE 6.—Iron ore production, shipment, and stocks

(Thousand metric tons)

	1959	1960	1961	1962	1963
Production:					
Mine-run ore	18,063	18,869	18,866	16,643	12,898

Concentrating	7,006	8,386	7,614	6,381	5,495
Total	12,961	13,543	13,086	11,431	8,590
Iron content	4,277	4,558	4,423	3,899	3,124
Shipments:					
Ore	12,714	13,601	12,964	11,092	8,517
Iron content	4,226	4,575	4,384	3,790	3,092
Stocks at yearend	1,476	1,099	1,301	1,947	2,280

In 1963 the iron content of domestic ore shipped was equivalent to 14 percent of the pig iron produced, compared with 28 percent in 1953. This decline has taken place despite a rationalization of the domestic industry initiated some years ago to amalgamate small mines and close marginal ones. The number of mines operating has been reduced from 90 in 1952 to about 30 in 1963. The share of domestic ore in total consumption may increase when the Staffhorst iron mine, which was discovered in 1959, comes into production. This deposit, with 37 percent iron content, was developed by a consortium of steel producers for an annual production of 8 million tons. By the end of April 1963, the shaft was down to a depth of 407 meters.

Percentage shares of selected mining districts in total production of mine run iron ore in 1963 were: Salzgitter 41; Ilsede 19; Dogger ore region 8; Siegerland-Wied 6; Osnabrucek 5; and Weser-Wiehengebirge 4.

In 1963 Sweden was the leading supplier of iron ore to West Germany with 29 percent of iron ore imports, followed by France with 25 percent, Brazil with 10 percent, and Liberia with 6 percent. Other suppliers included Peru, India, Venezuela, and Canada. It is expected that shipments from Liberia will increase because West German capital is being invested in developing a low-grade deposit there. French ore is shipped principally to the Saar.

Pyrite cinder is also an important iron source in Germany; in 1963, 3 million tons of pyrite cinders were used in sintering plants which produced nearly 25 million tons of sinter for blast furnaces.

Chromite and manganese ore requirements are met entirely by imports. About 90 percent of the chromite was used in making ferrochrome and chrome refractories; the balance presumably was used in chemical manufactures.

Iron and Steel.—*Production*—In 1963 West Germany produced about 8.2 percent of world pig iron and about 8.2 percent of world crude steel. Pig iron and steel output represented, respectively, 74.7 and 80.3 percent of maximum possible output. In 1963, output of steel was the lowest since 1960, when West Germany produced 10 percent of world total. Compared with 1962 figures, pig iron production dropped nearly 6 percent, crude steel 3 percent, and rolled steel 3 percent. In the last quarter of 1963, however, crude steel production exceeding the same quarter of 1962 by 4 percent, owing to increased orders in the third quarter. Thus, the production outlook was favorable at yearend. Total orders for 1963 were 492,000 tons above those

TABLE 8.—Maximum production capacity and actual production of pig iron and crude steel

Year	Pig iron [1]			Crude steel		
	Capacity (thousand metric tons)	Production		Capacity (thousand metric tons)	Production	
		Actual (thousand metric tons)	As percent of capacity		Actual (thousand metric tons)	As percent of capacity
1959	25,225	21,602	85.6	32,915	29,435	89.4
1960	27,130	25,739	94.9	35,335	34,100	96.5
1961	28,380	25,431	89.6	36,885	33,458	90.7
1962	29,880	24,251	81.1	38,030	32,563	85.6
1963	[2] 30,650	22,909	74.7	[2] 39,340	31,597	80.3

[1] Including spiegeleisen.
[2] Provisional.

Digitized by Google

of 1962, with foreign orders exceeding those of 1962 by about 1 million tons. Furthermore, prices firmed up from low discount prices that prevailed in midyear.

In 1963, Thomas pig iron constituted 62 percent of total pig iron output and open hearth pig iron supplied 29 percent. The share of Thomas pig has declined steadily from 70 percent of total output in 1959; that of open hearth has increased from 21 percent in 1959. Pig iron capacity was to be expanded to 32 millions tons in 1964. Nordrhein/Westfalen, where the Ruhr is located, is the foremost pig iron-producing State; the Saar ranked second. In 1963 these two States produced 68 and 14 percent of the total, respectively. Table 9 shows trends in production of crude steel.

TABLE 9.—Production of crude steel by processes

Type of process	1962		1963		Variation in 1963 in relation to 1962 (percent)
	Production (thousand metric tons)	Percent of total	Production (thousand metric tons)	Percent of total	
Open hearth	15,048	46.2	14,017	44.3	−6.9
Thomas	13,211	40.6	12,440	39.4	−5.8
Electric	2,567	7.9	2,647	8.4	+3.1
Oxygen	1,684	5.2	2,453	7.8	+45.7
Other	53	.1	40	.1	−24.5
Total	32,563	100.0	31,597	100.0	

Use of sinter in blast furnaces continued to increase. During the year sinter constituted 54 percent of the blast furnace charges. Despite the decline of total steel output, shares of oxygen and electric steel in total production increased; the former by 46 percent. This trend has been apparent for a number of years; for example production of electric steel in 1963 was 4.6 times that of 1953. It is expected that in terms of tonnage, oxygen steel will exceed electric steel in 1964.

While total output of rolled steel declined in 1963—bars by 4 percent, structural steel and sections by 5 percent, plates by 13 percent, and hot strips by 7 percent—output of medium and thin sheets increased by 5 percent and 12 percent, respectively. The continued increase in production of flat products has been apparent since 1953. Of total investment of $2.4 billion in the German iron and steel industry during 1955–62, $565 million, or 23 percent, was invested in flat mills.

Consumption and Trade.—Flat products constituted the largest iron and steel commodity group exported in 1963. In 1963 EEC received 58 percent of West Germany's export of pig iron and ferroalloys; 62 percent of the ingots, blooms, and billets; and 54 percent of finished rolled steel including cast iron and steel pipes and forged steel.

TABLE 11.—Composition of rolled steel produced for selected years

(Percent)

Type of product	1953	1959	1961	1962	1963
Flat products	40.6	44.6	43.8	47.3	46.9
Bars and rods	29.8	26.6	27.6	24.6	24.4
Wire rods	9.0	10.3	9.6	9.6	10.6
Rails	5.4	3.9	2.8	2.6	2.7
Sections	10.1	8.3	9.6	9.6	9.1
Pipes	5.1	6.3	6.6	6.3	6.3

Medium and thin sheets, tinplate, and other sheets constituted the largest import commodity group, followed by bars, wire bars, coils, and plates. Common Market countries, particularly Belgium-Luxembourg and France, were principal suppliers and accounted for 74 percent of rolled steel.

Apparent consumption of steel in West Germany during the first three quarters of 1963 was at an annual rate of 28,700,000 tons, on the basis of ingot steel, or an average of 495 kilograms per person. In arriving at this general figure only ECSC treaty items have been included in imports; however, imports of nontreaty items were only about 1 percent of total imports. Orders of finished rolled steel for domestic consumption in 1963 totaled 15,725,000 tons.

Principal companies and plants.—There were 72 iron and steel producing firms (exclusive of subsidiaries) in West Germany in 1963, of which about 20 had integrated operations. Huetten und Bergwerke Rheinhausen is the steelmaking enterprise of Krupp. The Bochumer Verein, with which Capito and Klein merged in 1962, is a subsidiary of Huetten und Bergwerke Rheinhausen. In 1961, the first eight companies listed in table 13 produced 62 percent of all crude steel in the country, and their share of total production in 1963 was probably about the same.

TABLE 12.—Iron and steel trade in 1963

Type of product	Imports		Exports	
	Metric tons	Percent	Metric tons	Percent
Ingots, blooms, and billets	232,126	5.46	1,128,300	15.43

TABLE 13.—Selected iron and steel companies

Company and location	Production (thousand metric tons)		Plant location	Principal facilities
	1961	1963		
August-Thyssen Huette A. G., Duisburg-Hamborn.	2,986	3,171	Duisburg-Hamborn.	Coke ovens; sintering plants; blast and open hearth furnaces; Thomas converters; and rolling mills including section, hot strip, and cold strip mills.
Phoenix-Rheinrohr A. G., Duesseldorf.	3,206	2,950	Duisburg-Ruhrort/ Meiderich, Muelheim/Ruhr, Dinslaken, Duesseldorf -Lierenfeld, Immigrath, and Hilden.	Sinter plants; blast and open hearth furnaces; bessemer oxygen converters; plate, merchant, and strip mills; and seamless tube plant.
Kloeckener-Werke A. G., Duisburg.	2,516	2,561	Bremen and Hagen-Haspe.	Coke ovens; sintering plant; blast, open hearth, and electric furnaces; rolling mills including section, bar, wire rod, hot strip, cold-rolling, and wire mills; steel foundry; wheel and tire plant; hot dip and electrolytic tinning lines.
Hoesch Westfallhuette A. G., Dortmund.	2,290	2,300	Dortmund	Blast and open hearth furnaces; Thomas steelworks; rolling mill including section, merchant, wire rod, wide strip, and cold-rolling mills; hot dip and electrolytic tinning lines.
Dortmund Hoerder Huettenunion A. G., Dortmund.	2,839	2,270	Dortmund and Hoerde.	Ore-sintering plant; blast and open hearth furnaces; Thomas converters, rolling mill for heavy steel, and steel foundry shop.
Hüetten-und Bergwerk Reinhausen, A.G., Rheinhausen-Neiderrhein.	2,214	(1)	Rheinhausen	Blast, open hearth, and electric furnaces; Thomas converters; section, rod, and plate mills.
Huettenwerk Oberhausen A. G., Oberhausen/Rhineland.	2,190	1,882	Oberhausen and Gelsenkirchen.	Blast and open hearth furnaces; Thomas steel plant; and rolling mills including merchant, wire, plate, and sheet mills.
Mannesmann A. G., Dusseldorf.	2,354	(1)	Huckingen, Grillo, Finke Finnentrop, and Hahnsche Werke.	Blast furnaces; Thomas steel and open hearth works; electric furnaces; rolling mills including section, medium plate, tube plate, sheet bar, sheet and cold-rolling mills; galvanizing shop; and tube plants.
Huettenwerke Salzgitter, Salzgitter-Druette.	1,619	1,350	Salzgitter and Watenstedt.	Coke ovens; blast and open hearth furnaces; Thomas converters, blooming, slabbing, and continuous billet and bar mills; and heavy and medium plate mills.
Bochumer Verein fuer Gusstahlfabrikation A. G., Bochum.	1,477	(1)	Toisdorf and Osnabrueck.	Blast, open hearth, Lenz-Donowitz (LD), and electric furnaces; steel foundries; rolling mills including wire and cold-rolling mills; and press and forge shops.
Roechling'sche Eisen und Stahlwerke G.m.b.H., Voelkingen-Saar.	(1)	2 1,000	Voelkingen-Saar	Coke ovens; sintering plant; blast, open hearth, and electric furnaces; Thomas converters; heavy, medium, and small section mills; hot strip and wire mills.
Ilseder Huette, Peine	875	(1)	Peine, Gross-Ilseder.	Coke ovens; sintering plant. blast and open hearth furnaces, Thomas converters, and rolling mills.
Rheinsche Stahlwerke, Essen.	921	770	Muelheim (Ruhr), Gelsenkirchen Oberkassel, Witten, and Remscheid.	Coke ovens; blast, open hearth, and LD furnaces; heavy and medium plate, bar, and wire rod mills; press and forge shapes; wheel and axle plants; and steel and pipe foundries.
Eisenwerk, Gesllschaft Maximilianshuette m. b. H., Sulzbach-Rosenberg.	704	654	Sulzbach-Rosenberg and Haidhof.	Blast, open hearth, and electric furnaces; Thomas converter, rolling mills including section, sheet, and bar mills; and foundry.

The High Authority of the ECSC on July 10, 1963, authorized the merger of August-Thyssen Huette (ATH) and Phoenix-Rheinrohr under certain specific conditions pertaining to a contract for delivery of hot-rolled strip by ATH to Huettenwerke/Siegerland. ATH complied with the conditions set by the Authority to reduce delivery of hot rolled strip by ATH to Huettenwerke/Siegerland, and this action prepared the way for the merger. The new company, with a total ingot capacity of about 8 million tons, will be the second largest producer in West Europe after FINSIDER, the Italian steel combine.

The High Authority also approved an agreement between Huettenwerke Salzgitter and Ilseder Huette designed to prevent the development of an excess production capacity for wire rod products. Salzgitter will build a new wire-rolling mill, and Ilseder Huette will refrain from building such a mill for 10 years. Under the agreement, Salzgitter, under its own name and for its own account, will sell rods rolled from its own billets and, under Ilseder Huette's name and account, will sell rods from billets supplied by this company. Ilseder Huette, in its own name and for the account of Salzgitter, will sell products rolled from the Salzgitter billets.[3]

Terms of an agreement between ATH, Mannesmann, and Huettenwerk Oberhausen for cooperation in hot- and cold-rolled wide strip production were published, but signing of an agreement has not been reported.

During the year, ATH was erecting at Hamborn an additional blooming mill train and a second wide strip mill, which will roll strips up to 2 meters wide. To meet steel requirements of these mills, the company in June 1962 brought two new oxygen Linz-Donawitz convertors into operation; each furnace has a daily capacity of 150 to 180 tons. Building of this new melting shop was phased ahead of the new rolling mills because available rolling-mill capacity was 3.7 million tons per year, compared with a steel production capacity, excluding the new plant, of 3,250,000 tons.

Both the Hüetten-und Berkwerk Rheinhausen and Bochumer Verein reported investment projects during the year. Rheinhausen's investments include completion of oxygen steel works, erection of a blast furnace, and blooming and medium section mills. Bochumer Verein will install facilities for hot-rolled strip up to 1.6 meters wide and for increased open hearth capacity at Bochum. The company also plans expansion of the cold-rolling mill plant at the Dusseldorf-Benrath works of the former Capito and Klein.[4]

Ferroalloys.—Data on production of ferroalloys other than blast furnace ferromanganese and spiegeleisen and the breakdown of "other ferroalloys" included in trade are not available. In 1962, Germany was a net importer of ferromanganese and "other ferroalloys" but a net exporter of spiegeleisen.

Several of the large iron and steel companies produce blast furnace ferromanganese and ferrosilicon. Among these are Phoenix-Rheinrohr A. G., at Duisburg, Huettenwerk Oberhausen A. G. at Oberhausen, Luitpoldhuette at Amberg, and August-Thyssen Huette at Hamborn. Gesellschaft fuer Elektrometallurgie, the largest ferrochrome producer, has a rated annual capacity of 75,000 to 100,000 tons.

TABLE 14.—Principal ferroalloy producers

Company	Plant Location	Type of products
Gesellschaft fuer Elektrometallurgie, Duesseldorf.	Weisweiler, and Nuer-emberg,	Refined manganese; low-carbon ferro-chrome; ferroalloys with tungsten, molyb-denum, boron, cobalt, columbium, tantalum, zircon, and phosphorus.
Herman C. Starck, Berlin	Goslar Laufenburg	Tungsten and ferrotungsten.
Badische Wolframerz-Gesellschaft, Solingen.	Solingen	High- and low-carbon ferrochrome, ferro-tungsten, and ferromolybdenum.
Theodore Goldschmidt, A. G	Essen	Ferroalloys with tungsten, vanadium, titanium, and other.
Metallwerk Dr. Alexander Nacker: Gesellschaft fuer Elektromet-alurgie	Munich	Refined manganese and silicon.
Phoenix-Rheinrohr A. G	Dusseldorf	Standard manganese.

Nonferrous Metals.—Practically all nonferrous metals are mined, but mine output does not meet domestic requirements. Domestic smelters met substantial percentages of copper, lead, zinc, and aluminum requirements; they recovered small but important quantities of bismuth, chromium, cobalt, tungsten, vanadium, cadmium, columbium, tantalum, and rare metals, chiefly from imported raw materials. Metals such as antimony, gold, mercury, nickel, magnesium, platinum, tin, titanium, and uranium were imported, principally in refined form.

Metallgesellschaft, with numerous subsidiaries and affiliated companies, produced the greatest variety of nonferrous metals. The Federal Government, through its controlling interest in Vereinigte Aluminium Werke, A. G. (United Aluminum Works, Inc.), was a producer of aluminum. Preussische Bergwerks-und Huetten-Aktiengesellschaft (Prussian Mining and Smelting Works, Inc.—Preussag) remained an important producer of lead and zinc and their semifabricated products, and byproducts. Preussag is a holding company which holds

TABLE 15.—Consumption of nonferrous base metals

(Metric tons unless otherwise stated)

Commodity	Consumption			Ratio of production to consumption, 1963 (percent)
	1961	1962	1963 [1]

interest in Unterharzer Berg- und Huettenwerks (57.1 percent) and Metallwerke Unterweser (100 percent) and owns many others. The Federal Government had a controlling interest in this concern until 1959 and still held a small share in 1963.

In addition to the principal primary nonferrous metallurgical plants listed in table 16, there were two dozen important secondary producers of nonferrous metals. Their products included aluminum, copper, cobalt, lead, zinc, magnesium, and tin.

TABLE 16.—Principal nonferrous metallurgical plants

Company	Type of plant	Annual capacity (tons)	Remarks
Aluminum:			
Vereinigte Aluminium Werke, A. G., Bonn:			
Lippewerk at Luenen	Alumina	130,000	
	Aluminum	39,000	
Erftwek at Grevenbroich.	Aluminum	30,000	Reduces alumina from Lippewerk.
Nabwerk at Schwandorf.	Alumina	110,000	Provides alumina for Innwerk.
Innwerk at Toeging	Aluminum	55,000	This plant has hydroelectric power.
Rheinwerk at Norf	do	44,000	There are 162 cells in 3 buildings and 2 smelting furnaces. Preburnt electrodes can be produced at the rate of 25,000 tons per year.
Alwerke at Bonn	do	3,000	High-purity aluminum.
Copper:			
Norddeutsche Affinerie, Hamburg.	Copper smelter, refinery, and rolling mill.	70,000 blister, 130,000 electrolytic refined, and 6,000 fire-refined copper.	This company, affiliated with Metallgesellschaft, A. G., is the largest copper refinery in the country. Besides copper and lead, the plant produces antimony, bismuth, gold, silver, tin, nickel, and cobalt.
	Lead smelter and refinery.	25,000	
Duisburger Kupferhuette, A. G., Duisburg.	Copper smelter, refinery, and rolling mill.	15,000 blister, 15,000 refined.	Chemical-metallurgical plants treat burned pyrite and recover gold, silver, cadmium, indium, and thallium. Annually 1,000 to 1,500 tons of cobalt also is recovered from burned pyrite.
	Zinc refinery	8,000	Treats zinc oxide clinkers produced during treatment of burned pyrite.
Metallhuettenwerke Luebeck, G.m.b.H.	Copper refinery	13,000	Recovers copper from burned pyrite blister, and scrap.
Bieber and Company, Kupferhuette Ertel.	do	(1)	Recovers copper from burned pyrite.
Lead-zinc:			
Unterharzer Berg-und Huettenwerke, Goslar:			
Plant at Oker	Lead smelter and refinery.	40,000	This plant smelts lead concentrate from Rammelsberg mine and recovers antimony, gold, and silver. Antimonial lead is also produced.
Plant at Harlingerade	Zinc smelter and refinery.	60,000	Smelts zinc concentrate from Rammelsberg ore using the New Jersey Zinc process with vertical retorts. It is the largest cadmium producer in the country and accounts for 60 to 70 percent of the country's mercury production. Germanium, indium, iridium, and thallium are other byproducts.
Harzer Berg- und Huettenwerke, Goslar:			
Plant at Clausthal	Lead smelter	30,000	Smelts concentrates from Bad Grund mine.
Plant at Lautenthal	Lead refinery	30,000	An important silver producer.

See footnote at end of table.

TABLE 16.—Principal nonferrous metallurgical plants—Continued

Company	Type of plant	Annual capacity (tons)	Remarks
Lead-zinc—Continued			
Stolberger Zink Aktiengesellschaft fuer Bergbau und Huettenbetrieb, Aachen:			
Plant at Muensterbusch.	Zinc smelter and rolling mill.	50,000	Slab zinc, mercury recovered as a byproduct.
Plant at Nievenheim.	Zinc smelter and sulfuric acid plant.		
Plant at Binsfeldhammer.	Lead smelter	65,000	Refined and high-purity lead, battery lead, antimonial lead, and silver byproduct.
Blei- und Silberhuette Braubach, G.m.b.H.: Plant at Braubach/Rhein.	Lead smelter	35,000	Owned by Metallgesellschaft, the plant treats ores and secondary materials and produces antimonial lead and byproduct silver. It can refine 2 million ounces of silver annually.
"Berzelius" Metallhuettengesell-schaft, G.m.b.H.: Plant at Duisburg-Wanheim.	Zinc smelter and refinery.	35,000 40,000	Produces standard- and high-grade zinc alloys and cadmium.
Metallwerke Unterweser, A. G.: Plant at Nordenham.	do	25,000	Treats concentrates, pyrite, ashes, and scrap.
Aktiengesellschaft des Altenbergs fuer Bergbau und Zinkhuettenbetrieb, Essen-Bergeborbeck: Plant at Borbeck.	Zinc smelter	30,000	Treats ores, concentrates, and ashes and produces slab zinc and zinc dust.
Precious and rare metals:			
Deutsche Gold- und Silber Scheidenanstalt (Degussa), Frankfurt/Main: Plants at Frankfurt and Hanau.	Blast and cupelling furnaces, silver and gold electrolytic refineries, etc.	----------	The company recovers precious metals from bullion and scrap material. It also produces high-purity indium, thallium, zirconium, thorium, etc.

[1] Data not available.

The Norddeutsche Affinerie produced roughly 60 percent of all refined copper. Vereinigte Aluminium Werke had 45 percent of the country's alumina and 82 percent of the aluminum capacity. The Binsfeldhammer plant of Stolberger Zink A.G., was the largest lead producer and the Harlingerade plant of Unterharzer Berg- und Huettenwerke, G. m.b.H., was the largest zinc producer.

In 1963 the metal content of ores produced in West Germany were equivalent to 18 percent of estimated lead consumption and 26 percent of the zinc consumption of the country. Lead-zinc ores also supplied antimony, cadmium, silver, and other metals.

The position of the nonferrous metal industry (including precious metals) improved during 1963, with the production index reaching 243, compared with 235 in 1962 (1950–100). Increased output and higher prices brought total sales to approximately US$1,490 million, compared with US$1,440 million in 1962. Of the output of semifinished products in 1963, copper and copper alloys accounted for 592,911 tons, aluminum for 255,047 tons, zinc for 69,611 tons, and lead for 43,287 tons. The industry had sharp competition from foreign producers, especially those of other Common Market countries. Because of imports there was a downward trend in production of zinc semimanufactures.

TABLE 17.—Production of ingots, semimanufactures, and castings of major nonferrous metals[1] and their alloys

(Thousand metric tons)

Commodity	1962	1963	Commodity	1962	1963
Nonferrous metals and alloys	1,171	1,217	Castings	271	279
Semimanufactures	960	975			

[1] Aluminum, copper, lead, and zinc.

Total consumption of primary and secondary nonferrous metals and alloys increased 0.5 percent in 1963. Supplies of tin, cadmium, and electrolytic manganese were low, but significant stocks of most nonferrous base metals were available through midyear.

TABLE 18.—Commercial stocks of nonferrous metals

(Thousand metric tons)

Commodity	Stocks			
	Dec. 31, 1960	Dec. 31, 1961	Dec. 31, 1962	June 1963
Aluminum (nonalloyed)	56.0	63.0	50.8	58.7
Refined copper	53.7	60.4	51.9	44.8
Lead	45.5	37.0	45.5	51.7
Zinc	39.8	45.4	41.4	58.1
Tin	2.0	2.1	1.6	1.3

In 1963 the value of imports of all base nonferrous metals, semifinished products, and ores and scrap totaled US$652 million, compared with US$677 million in 1962. Precious metal imports added US$146 million—gold US$72 million, silver US$53 million, and platinum group US$21 million. Of the 1963 imports of nonferrous metal ingots, semimanufactures, and scrap, copper accounted for 45 percent, aluminum for 17 percent, zinc for 6 percent, tin for 5 percent, and lead for 4 percent. Among the Common Market countries, Belgium-Luxembourg was a significant source of zinc, refined copper, aluminum semifinished products, cadmium, and cobalt.

A significant part of the production of nonferrous smelters and refineries is exported, principally as semifinished products; nonferrous metal exports totaled US$322 million in 1963. Copper (including semimanufactures and scrap) accounted for 33 percent of the value. Main recipients in the Common Market were the Netherlands for refined copper and semimanufactures and aluminum and Belgium-Luxembourg for refined lead. France imported slab zinc and refined lead.

Aluminum.—Operation of the "Rheinwerk" aluminum plant of Vereinigte Aluminum Werke at Norf increased aluminum production in 1963. About 367,000 tons of domestically produced aluminum was available, compared with 315,300 tons in 1962. Increased use of aluminum in construction led to a 4-percent increase in output of semimanufactures from 245,829 tons in 1962 to 255,047 tons in 1963—174,000 tons rolling mill products, 58,000 pressings and forgings, and 23,000 conductor material. Compared with 1962 figures, rolling mill

Digitized by Google

products increased by 7 percent, but pressings and forgings and conductor material both decreased by about 11 percent.

The European Economic Commission grants West Germany quotas for import of aluminum from countries other than the European Economic Community at a preferential import duty rate of 5 percent (compared with 9 percent full rate) and quotas for aluminum scrap at 0.75 percent import duty. For the first 6 months of 1964, the Commission granted Germany a 60,000-ton quota for aluminum and a 7,500-ton quota for aluminum scrap at these preferential rates. Since May 1, 1962, imports of aluminum scrap from the Community have been duty-free.

To meet competition from imports, West German smelters, starting June 1, 1963, granted a rebate of $25 per metric ton of primary aluminum from the $540 per ton price. The rebate is revocable at any time. In 1963 the price of imported primary aluminum, including customs duty and equalization tax on imports, remained at $514.

Per capita consumption of primary and secondary aluminum in 1962 was 7.5 kilograms, compared with 13.4 kilograms in the United States.[5] Transport accounted for 24.7 percent, electrical engineering for 17.5 percent, canning and packaging for 9.6 percent, and building for 6.7 percent of total consumption. The share of the building industry was much less than in the United States but it is expected to increase and contribute to an anticipated rise in the total consumption of the country.

Copper.—All of West Germany's 1963 copper mine production was derived from lead-zinc ore and pyrite. Imported copper concentrate, cupriferous pyrite, and pyrite cinder were smelted almost entirely in the Norddeutsche Affinerie for production of blister copper. Refined copper was produced from this blister and imported copper ingots, from scrap, and by remelting refined copper.

Of the total 1963 refined copper production, 235,207 tons was electrolytically refined and 67,611 tons was fire refined. Copper semimanufactures output was 592,911 tons, 2.8 percent higher than in 1962.

Since the second quarter of 1961, consumption of refined copper has declined steadily. Of the total consumption of 621,400 tons in 1962, about 370,000 tons, or 60 percent, was supplied by copper content of imported ore, net imports of blister, and refined copper, scrap, and matte. Domestic scrap generation accounted for much of the remainder of the total consumption.

Lead and Zinc.—In 1963 there were 8 lead-zinc mines in operation, all of which were directly or indirectly connected with smelters; in 1957 there had been 21 operating mines. Employment in lead-zinc mines was 3,000, or about one-third of that of a decade ago. Nearly one-third of the lead produced by smelting of ore in 1963 was supplied by domestic ores; the figure for zinc was closer to 75 percent, compared with nearly 66 percent in 1962. The increase in mine production of zinc in 1963 was due to operation of a new beneficiation plant at the Sachtleben pyrite mine at Meggen, starting in July. This mine is expected to be an important source of zinc ore.

[5] Aluminium. January 1964.

Digitized by Google

The slightly increased domestic mine output of lead did not quite balance the lower imports, so that primary lead smelter output was 6 percent lower in 1963. Secondary lead output, however, increased sufficiently to more than balance the lower primary smelter output. Increased imports of lead bullion coupled with the overall increase in smelter output made more lead available to consumers in 1963 than in 1962. Smelter zinc production was the lowest since 1955, resulting also in reduced cadmium production.

Production of semifinished products of both lead and zinc declined—lead from 47,003 tons in 1962 to 43,287 tons in 1963, and zinc from 75,641 tons in 1962 to 69,611 tons in 1963. Imports of Yugoslav zinc sheets are cited as a cause of the decline.

Other Nonferrous Metals.—A small amount of primary tin was produced by the Norddeutsche Affinerie. It is estimated that 30 percent of the annual consumption has been used for tinplating, and the bulk of the remainder in making solder, tin bronze, babbitt metal, pewter, and type metal, all largely for export. Although tin imports in 1963 were lower than in 1962, production of tin alloys and solders increased from 17,216 metric tons in 1962 to 18,535 metric tons in 1963. However, requirements for tin in making electrolytic tinplate have declined because of technological improvements in tinplating.

In 1963, 373 tons of magnesium semifinished products and 31,614 tons of magnesium castings were produced from imported metal.

Uranium was mined by Gewerkschaft Brunhilde at Ellweiler in an opencast mine. The ore in this mine contains about 0.12 percent U_3O_8 and is treated in a nearby mill. Both acid and alkaline processes are used. Another company, with a fluorspar mine near Waelsendorf in Bavaria, was engaged in uranium exploration in 1962; the property may have produced ore in 1963.

Enriched-uranium fuel elements were made by Nuklear-Chemie und Metallergie, G.m.b.H., at Wolfgang near Hanau from imported material. This was the only uranium processing in the country.

NONMETALS

West Germany produced a fair range of nonmetallic minerals and quarry products, but for many items such as asbestos, cryolite, industrial diamonds, magnesite, mica, phosphate rock, and sulfur, it has depended entirely on imports. During 1959–62 there has been a continuous increase in production of the raw materials of the building industry. Construction value attained a new record of $14,600 million in 1963. Fluorspar, slate, and quartzite output dropped during this period; no significant trend is shown in other commodities, except an increase in salt production.

The value of nonmetals produced in 1963 is not yet available, but in 1962 the value of these minerals, exclusive of building raw materials, totaled about $195 million. Potash and salt accounted for 49 percent and 16 percent of the total. Building raw materials (stones, sand and gravel, lime, gypsum, slate, lava, and pumice, the latter used essentially as a building material) were valued at $545 million. Stones, lime, and sand and gravel accounted for 43, 25, and 22 percent of this total. Cement added another US$400 million to the value

Digitized by Google

of building material. However, some of the cement is produced from slags rather than from quarry products.

In 1963 West Germany was a net exporter of barite, cement, clays, fluorspar, gypsum, potash, pumice, quartz and quartzite, salt, crushed rock, and gravel. Import and export values of nonmetals totaled approximately US$163 million and US$106 million, respectively. Among imports, phosphate rock US$25,428,000; asbestos US$20,169,000; pyrite US$19,386,000; marble and other stone US$13,118,000; crushed rock and gravel US$11,138,000; magnesite US$9,109,000; and sulfur US$7,055,000; were the most important items. Potash, cement, and barite were valued at US$49,318,000, US$11,480,000 and US$2,199,000, respectively.

Cement.—The production of cement has shown a continuous increase in the last decade, with the 1963 output more than twice that of 1954. The ratio of portland cement to total output is not available for 1963 but probably was about the same as the 72 percent in 1962.

In 1962, nearly 28.6 million tons of cement was available to the economy. Price of portland cement packed in bags in lots of 10 tons, f.o.b. Essen, has been US$17.50 per ton since 1960.

In 1963, 93 cement plants were reported in operation. At the end of 1961 West Germany had a production capacity of 30 million tons of cement; plans were to increase capacity to 33 million tons by the end of 1963.

TABLE 19.—Cement production,[1] by types

(Thousand metric tons)

Type of cement	1959	1960	1961	1962
Portland	16,601	18,063	19,500	20,739
Eisenportland (iron portland)[2]	3,187	3,477	3,788	3,936
Blast furnace[3]	2,025	2,466	2,832	2,873
Other cement and cementlike mortar	1,039	899	1,024	1,045
Total	22,852	24,905	27,144	28,593

[1] Data for 1959 exclude Saar and West Berlin; 1960–63 data exclude West Berlin.
[2] Eisenportland contains at least 70 percent by weight of portland cement clinker and not more than 30 percent granulated basic blast furnace slag.
[3] Blast furnace cement may contain 15 to 99 percent portland cement but in practice carries 40 to 50 percent.

During the last 5 years, although production of cement increased by 34 percent, the labor force did not increase proportionately. There were 22,347 workers in the cement industry in December 1963, only slightly more than the 21,970 recorded in 1959.

Although cement plants were located throughout the country, there was a concentration in the Beckum-Lippstadt-Padeborn area of Nordrhein-Westfalen State. In 1956, 41 cement plants with 38 percent of the total capacity were there. Other large producers were in the Osnabruck and Hannover areas; the Elbe estuary; the Neckar, Lahn, and Main Valleys; and Bavaria. The two largest companies were Portland Zementwerke Heidelberg, A.G. (Heidelberg Portland Cement Works, Incorporated), and the Dyckerhoff Portland Zementwerke, A.G. (Dyckerhoff Portland Cement Works, Incorporated).

Clays and Clay Products.—Domestic clay output met requirements for making bricks and fired clay products such as earthenware, stoneware,

Digitized by Google

vitrified porcelain, and tiles. Production of brick has shown a steady increase from 4,912,000 cubic meters in 1959 to 15,430,000 cubic meters in 1962. West Germany also produced all types of refractory products; output totaled 2,476,000 tons, with a value of about US$130 million, in 1962.

Most of the kaolin and all of the bleaching clays were produced in Bavaria. In 1962, 41 percent of the so-called special clays were produced in Rhineland-Pfalz, 21 percent in Nordrhein-Westfalen, and 19 percent in Bavaria. In 1963, kaolin imports exceeded exports, while refractory and other clay exports were more than twice the imports.

Fertilizer Raw Materials.—The West German fertilizer chemical industry was a highly developed branch of the economy, with plants to produce major types of fertilizers (nitrogenous, phosphatic, and potassic), singly and in combination. The value of the products of the fertilizer industry was US$437.5 million in 1962. Of the necessary raw materials, phosphate rock and most of the sulfur had to be imported.

The small growth in West German potash production in 1961 was followed by a decline in 1962, in both production and exports. According to an industry spokesman, Canadian potash was competing effectively with West German potash, especially in the Far East. In 1963, however, production was almost the same as in 1962, and there was a significant improvement in exports. The States of Niedersachsen and Hesse in 1962 produced 57 and 39 percent of the total output, respectively; the small remainder was accounted for by Baden-Wuerttenberg.

TABLE 20.—Chemical fertilizer production

(Metric tons)

Type of fertilizer	1962	1963
Potash, K_2O equivalent	[1] 1,937	[1] 1,948
Potash salt to 42 percent K_2O	430	383
Potassium chloride over 42 percent K_2O	1,228	1,309
Potassium sulfate	166	150
Other potash salts	72	71
Phosphatic, contained P_2O_5:		
Superphosphate	51,946	53,411
Ground Thomas slag	399,400	431,115
Chemically combined	265,394	284,284
Other	67,285	74,358
Nitrogen, contained N:		
From synthetic ammonia	730,034	756,759
From coke and gas works	105,768	103,633
Calcium cyanamide	83,127	90,090
Chemically combined	254,280	270,258

[1] Totals include a small quantity of raw salt (Hederich-kainite).

Source: 1962 data from Industrielle Produktion 1962, Reihe 3, page 3; 1963 data from Produktion ausgewaehlter industrieller Erzeugnisse, Reihe 2, December 1963, pages 6 and 8.

Domestic shipment of potassium fertilizers in the fiscal year July 1, 1962, to June 30, 1963, totaled 1,099,831 tons, compared with 1,038,808 tons in 1962. This was equivalent to 72.9 kilograms per hectare of arable land, compared with 70.6 kilograms in 1960–61. A subsidy on use of fertilizer, which was set at 9.6 percent during 1962, was eliminated on May 1, 1963.

TABLE 21.—Principal crude potash producers in 1962

Company	Production (metric tons)		Remarks
	Mine-run ore	K_2O equivalent	
Vereinigte Kaliwerke Salzdetfurth, A.G.	6,367,000	665,519	Company operates 4 underground mines and plants at Hattorf in Hesse and Salzdetfurth, Sigmundshall, and Hansa in Niedersachsen.
Wintershall, A.G	6,812,374	596,851	Production is from 4 mines. The largest is Heringen (mainly carnallite) in Hesse. Others are Neuhof in Hesse and Bergmanssegen-Hugo (largely sylvanite) and Hildesia Mathildenhall in Lower Saxony.
Burbach Kaliwerke	2,596,450	350,041	This company is owned 75 percent by Wintershall. Produces from 3 underground mines: Siegfried-Giessen, Niedersachsen-Rietel, and Konigshall-Hindenburg (largely sylvanite) all in Niedersachsen.
Kali-Chemie, A.G	1,411,905	146,230	The company is associated with Deutsche Solvay-Werke G.m.b.H, the large salt and chemical producer. Produces ore (mainly sylvanite) from Friedrichshall mine in Niedersachsen.

Sales of potash were handled by Verkaufgemeinschaft Deutscher Kaliwerke (Sales Association of the German Potash Works), a syndicate that was formed in 1955 for a 5-year period with offices in Hannover. The association was licensed in 1961 for an additional 3-year period from December 1962 to December 1965.

Thomas slag, the only phosphorus-bearing fertilizer raw material produced in West Germany, was supplemented by imports of phosphate rock. In 1963, 3,054,000 tons of Thomas slag was produced containing about 469,000 tons of P_2O_5. Of this, 2,591,000 tons was shipped to slag mills presumably for fertilizer use. Trade of Thomas slag during 1963 was almost in balance. Apparent consumption of phosphate fertilizers in 1961–62 and 1962–63 in terms of P_2O_5 content was 633,927 and 718,764 tons, respectively.

Salt.—The bulk of West Germany's salt output in 1962 originated in Nordrhein-Westfalen (48.5 percent), Baden-Wuerttemberg (33.9 percent), and Niedersachsen (17.5 percent). In the same year, one company, Deutsche Solvay-Werke, G.m.b.H., produced 48.48 percent of total output.

Sand.—The value of all sands produced in 1962 totaled US$136 million. Following the trend of construction activity, production of sand used in building and roadmaking increased at an average rate of 12 percent per year during 1954–62. Of the total 1962 building sand output, 11,327,000 tons was used in roadbuilding and the remainder in construction. Quartz and quartz sand and glassmaking and molding sand are also produced. Most of the quartz sand is used in glassmaking.

Stone.—Production data tabulated on stone refer to stone used for making roads, railroads, and waterworks, but exclude dimension stone. The production of 80 million tons of stone valued at $262 million (calculated on the basis of 1962 average values of $3.28 per ton) represents an increase of 10 percent in tonnage. Of 1962 output, 38,215,000 tons was classified as aggregate for highway construction, 14,034,000 tons as chips of better quality stone, 7,560,000 tons as roadbase, and

Digitized by Google

4,592,000 tons for use in tar and asphalt material. The remainder was higher grade material such as riprap, stone for harbors and waterways, and roadbase.

TABLE 22.—Principal rock salt producers

(Metric tons)

Company	1962 production	Remarks
Deutsche Solvay-Werke, G.m.b.H	2,210,780	Mines salt (200 meters thick) in Borth and Wallach underground mines at depth of about 850 meters. Mines are in Nordrhein-Westfalen State.
Staatl. Saline Friedrichshall	661,130	A 26-meter salt bed is mined at about 200-meter depth in "Koenig Wilhelm II" mine in Baden-Wuerttemberg State.
Salzwerk Heilbronn	(1)	Mine working a 40-meter salt bed in Baden-Wuerttemberg State.
Gewerkschaft Braunschweig-Lueneburg	243,472	Salt is recovered as a byproduct of potash from Grasleben and Heidewinkel mines in Niedersachsen. This company is a subsidiary of Salzdetfuerth A.G.
Burbach-Kaliwerk A.G	268,102	A subsidiary of Wintershall A.G., works the Asse underground mine in Niedersachsen State.
Mariaglueck Bergwerksgesellschaft m.b.H	287,244	A subsidiary of Salzdetfuerth A.G., the company also produces potash in the Mariaglueck mine in Niedersachsen State.

[1] Data not available.

Sulfur.—Domestic production of contained sulfur in 1963 is estimated at about 265,000 tons—177,000 tons of sulfur in pyrite, and about 88,000 tons of elemental sulfur recovered from various chemical processes and petroleum refineries.

The local market for elemental sulfur continued to expand, with imports 33 percent greater than in 1962 and 82 percent greater than in 1961. The increase was due to the trend away from using pyrite in making sulfuric acid and an increase in sulfuric acid production. In 1962, 13 percent of sulfuric acid was made from elemental sulfur, compared with 9 percent in 1961. Pyrite, still the most important raw material, accounted for 61 percent of acid production in 1962, compared with 67 percent in 1961. Smelter gases and other raw materials such as hydrogen sulfide, ferrosulfate, and spent oxide accounted for the remainder.[6]

TABLE 23.—Salient statistics on sulfur, pyrite, and sulfuric acid

(Metric tons, unless otherwise specified)

	1961	1962	1963
Sulfur:			
Production	84,190	90,666	----------
Net imports	160,252	219,659	292,288
Consumption	228,083	288,621	----------
Exports	16,358	21,704	11,715

Despite competition from elemental sulfur, the market for pyrite, both domestic and imported, remained assured. The bulk of the domestic production has been from the Meggen mine of Sachtleben A.G. in Westfalen, a subsidiary of Metallgesellschaft A.G., which is interested in the zinc content of the ore. The Duisburger Kupferhuette A.G., the major firm processing pyrite, was owned by the three largest sulfuric acid producers, thus providing a continuing market for pyrite.

A notable change in 1963 import sources was the large increase in tonnages received from Norway and reduction in imports from Cyprus and Turkey.

Other Nonmetals.—West Germany remained an important consumer of abrasives and industrial diamonds. Stone production statistics list millstones and whetstones; in 1963, 192 and 362 cubic meters of these abrasive stones were produced, respectively. Some of the country's output of quartz and quartz sand was used as abrasives.

The Meggen pyrite-barite mine of Sachtleben in Westfalen, with a production of 173,986 tons of salable barite, was the largest producer in 1963. Vereinigte Werke Dr. Rudolf Alberti and Company was the second largest barite producer with a total of 111,363 tons from three mines in the Bad Lauterberg area (Harz), four mines in Sontra, Hesse, and three mines in the Bayreuth area of Bavaria.

MINERAL FUELS

In 1963 coal and lignite supplied 63.7 percent of West Germany's energy consumption, petroleum and natural gas supplied 33.4 percent, and the remainder was provided chiefly by hydropower and fuelwood. Net fuel imports totaled 53,874,000 tons of standard coal equivalent, or 21.6 percent of total energy consumption.

There has been a significant change in the energy supply pattern of West Germany. Although energy consumption has increased, coal has not shared in the increase and its relative position in the total energy picture has deteriorated. The greatest inroads have been made by heavy and light fuel oils, the consumption of which increased from 2.1 million metric tons in 1955 to 24.4 million tons in 1963. In 1955, energy derived from oil constituted only 8.4 percent of total energy consumption, compared with 32.6 percent in 1963.

TABLE 24.—Domestic energy consumption [1]

(Thousand metric tons of standard coal equivalent)

Year	Coal	Lignite and pech coal	Total coal	Petroleum	Hydropower [2]	Gas [3]	Wood and peat	Other	Total
1959	119,654	30,173	149,827	36,782	5,154	820	2,122	163	194,868
1960	126,313	30,966	157,279	46,510	6,513	932	1,798	209	213,241
1961	121,399	31,136	152,535	55,633	6,535	1,051	1,642	189	217,585
1962	122,869	32,579	155,448	68,457	5,827	1,339	1,745	204	233,020
1963	124,232	34,276	158,508	81,332	5,508	1,859	1,870	223	249,300

[1] Domestic production plus imports minus exports adjusted for stock variation. Imports included imports from East Germany and direct shipments of U.S. coal to U.S. troops stationed in Germany; exports include shipments to West Berlin and East Germany.
[2] Excludes power used by pumping plants.
[3] Unassociated and associated natural gas and drained gas from coal mines.

The pressure for establishing an energy policy has been generated mainly by the coal industry which, particularly since 1958, has encountered severe competition from other energy sources. The Government's overriding policy is that energy should be made available at the lowest cost and the public should have freedom of choice in the fuel it uses. Consistent with this, it is the stated objective of the Government to maintain an annual coal output of 140 million tons. This policy was reiterated during the energy debate of March 29, 1963, in the Bundestag (Lower House of Parliament), although it was made clear that the Government was not guaranteeing this level of production, but looked upon it as a desirable goal. The Government has taken a number of steps to assist the industry, but has avoided quantitative control on petroleum imports except as a last measure. Nonetheless, the Government early in 1963 issued a regulation which subjects to Government approval all import contracts for crude oil and several oil products for periods longer than 9 months, in contrast to the less restrictive previous policy, which required approval only for agreements of 2 years or more duration. This enabled the Government to introduce quota restrictions on shorter notice, without increasing liability for contract cancellations. The coal industry has consistently favored licensing of crude and fuel oil imports and limitations of the refining capacity to the expected expansion of energy consumption.

Several other measures were taken to protect the coal industry. A protective tariff of $5 per ton on coal imports from countries other than the ECSC countries, which was first put into effect on February 16, 1959, was extended to the end of 1964. Annually, however, a duty-free quota is established. On April 11, 1963, the $5-per-ton duty on heavy fuel oil and $2.50-per-ton duty on light fuel oil established on May 1, 1960, were extended for 6 years. The duties will be applied at the original rates until April 30, 1967, and reduced to half these rates between May 1967 and April 1969. On March 1, 1962, railroad freight rates for transport of coal by rail and inland waterways were reduced. There were press reports in October 1963 that the Federal Government was considering a subsidy for new powerplants which would use domestic hard coal as a fuel. However, by yearend no subsidy program was implemented.

Government and industry did not rely on protective measures alone to assist the industry, but continually have attempted to increase the efficiency of the industry. For this purpose a Law for Promotion of Coal Mines Rationalization came into force on September 1, 1963. The aims of the law were twofold: First, to create larger and more efficient units by combining neighboring mines and by increased mechanization and automation; and second, to close mines, which, because of unfavorable seams or poor plant facilities, cannot be operated economically even with the application of the best technical and managerial methods. To carry out this program, the law created for a period of 5 years an Association for Rationalization of Coal Mines (Rationalisierungsverband des Steinkohlenbergbaus). The Association is a public corporation, administratively independent but supervised by the Ministry of Economy. Membership in the Association is compulsory for companies that produced an average of 100,000 tons

Digitized by Google

or more of marketable coal per year in 1959–61. By provision of the law, the Federal and State Governments guarantee loans for investment in the industry, up to US$375 million. In case of mine closures, a premium of US$6.25 per ton of average annual mine production during 1959–61 is to be paid, one-half by the Federal Government and one-half by the organization from funds obtained by an assessment on the membership. A supplementary premium is to be paid for operators who completely quit coal mining. The total cost of the premiums is expected to be about US$31 million.

Elements of the foregoing energy policy have been regarded as temporary in nature and were intended to meet the immediate problems of the coal industry. Formulation of a long-term policy awaits determination of a unified European Economic Community energy policy. In the immediate future and when the full effect of the mechanization program is felt, the coal industry should be able to maintain the desired level of output. It is felt, however, that future increments in energy consumption will be met primarily from oil.

Bituminous Coal and Anthracite.—*Production.*—Production of coal increased by about 1 million tons (0.7 percent). The increase is attributed largely to an additional 1.6 workdays; the daily rate of production in 1963 was only 453 tons more than 1962. Of the total output, 75 percent was "Flammkohle and Fettkohle," which are medium to high-volatile coking coals; 3.83 percent was "Esskohle," or bituminous to semianthracite, and 9.6 percent was semianthracite to anthracite.

As in previous years, the Ruhr accounted for the bulk of the output, followed by Saar and Aachen. The Ruhr has 93 percent of the total measured and indicated reserves which are estimated at 222.9 billion tons to a depth of 2,000 meters. The balance of the reserve is in the Aachen area with 4 percent, Saar 2.9 percent, and Lower Saxony 0.1 percent.

Coal was produced by relatively few companies with large individual outputs, and the trend was toward still larger operations. In 1962, 36 firms had annual production exceeding 1 million tons; 20 of these produced over 2.5 million tons. In the same year, 75 percent of the total output was obtained from 70 mines, each producing more than 1 million tons. Fifty-seven mines produced 76 percent of the Ruhr's output. Average per-man output increased about 7 percent.

TABLE 25.—Production of coal, coal briquets, and coke in 1963, by areas

(Thousand tons)

[1] Excluding Saar.

Because of industry's own efforts in rationalization, the number of operating mines has declined. Since 1958, 30 mines with a productive capacity of 13.5 million tons have been closed; 12 of these closed between April 1962 and mid-1963. West German coal mines are relatively deep.

Availability, Disposal, and Trade.—It is difficult to assess precisely domestic coal consumption. In 1962, coal sales in West Germany, mine consumption, including miners' household and mine power plant, and coal delivered to coking plants totaled 131,788,000 tons. But all of the coke produced (43,198,000 tons, excluding that produced in gasworks) was not consumed domestically. Deducting coke exports, converted to coal, about 118 million tons of bituminous coal and anthracite was consumed in the domestic economy. Of the total output of coal in 1963, 99,345,000 tons, or 70 percent, was shipped for conversion to coal briquets, coke, and electricity.

The stocks of coal and coke at the end of December 1963 stood at 3,785,000 tons (2,381,000 tons of coal and 1,404,000 tons of coke), compared with 9,923,000 tons in 1962 and 11,988,000 tons in 1961. The 8-million-ton reduction in stock during 1962 and 1963 resulted chiefly from sales during the abnormally cold winter of 1962–63.

[1] Trade figures for coal and coke differ slightly from those given in metal and mineral trade tables, presumably owing to revisions.
[2] Includes small quantities used by the coke plants and others.

Source: Jahrbuch des deutschen Bergbaus, 1962 and 1963.

Although West Germany has ranked as an important coal exporter in Europe, it also has regularly imported coal. The Common Market countries received 86 percent of the coal export; France is the largest recipient. Coke exports to the Common Market, principally France and Belgium-Luxembourg, comprised 73 percent of the total. Of the coal imports, 61 percent were from the United States and 24 percent were from the Common Market. Imported coal may be marketed only in the north coastal areas of the country. Coal shipments between

Digitized by Google

East and West Germany and shipments to West Berlin are also significant.

Although there is a $4-per-ton duty on coal imports, the Government establishes annually a duty-free quota. For 1963 and 1964 this quota was 12,023,000 tons, with 10,040,000 tons as the U.S. share.

Marketing and Price.—In March 1963, the High Authority of the European Coal and Steel Community (ECSC) approved an arrangement under which two independent sales agencies of almost equal magnitude were established to market Ruhr coal. A previous proposal of the Ruhr coal producers to establish a single sales agency had been rejected both by the High Authority and by the Court of Justice of the ECSC during 1962.

The two sale agencies established were the Ruhr Coal Sale Agency Praesident and the Ruhr Coal Sale Agency Geitling. The High Authority reportedly will insure that these organizations meet the requirements of minimum competition required by the Treaty. A decision of December 11, 1963, permitted coal users with annual consumption exceeding 30,000 tons to buy their coal either directly from one of the two sales agencies or from wholesalers. Sales to iron and steel plants and their coke ovens and to the State railways were reserved to the two sale agencies.

The prices of various sizes of coal and coke at mine at the end of 1963, in U.S. dollars per ton, follow: Fettkohle (bituminous coking coal) $16.62 to $17.87; Esskohle (bituminous to semianthracite) $14.87 to $17.75; anthracite $26.25 to $26.62; and coke $25.25. Coal prices were increased 2 to 3 percent for most coal grades after new wage contracts were concluded in 1962.

Digitized by Google

The average c.i.f. values per ton of bituminous coal and anthracite (including briquets) imported in 1963 in U.S. dollars per ton follow: Belgium-Luxembourg $16.12; France $15.50; Netherlands $14.50; Poland $14.75; United Kingdom $10.68; United States $14.82; and the U.S.S.R. $10.05.

Labor.—In 1963, average employment in the bituminous coal and anthracite industry totaled 421,337, consisting of 316,916 underground and surface workers, 27,714 workers in coal washeries, 26,335 workers engaged in capital investment and general services, and 50,372 staff members. Labor employed in the industry continued to decrease, but the rate of decrease fell. For surface and underground workers, employment in 1963 was 6 percent less than in 1962, compared with a decrease of 8 percent in 1962 with respect to 1961.

Total [1]	6,840	6,337	6,136

[1] Total includes coal washery, general services, and mine staff.
[2] Includes about 50 underground workers and staff ranging from 3,152 in 1960 to 3,259 in 1963.

Source: Zahlen zur Kohlenwirtschaft, volume 63, February 1964.

A new wage contract was agreed upon in September 1963 by the Employers Association of the Ruhr Coal Industry and the Mine and Energy Workers Union which provided increases for 350,000 hourly

Digitized by Google

and 40,000 salaried employees. The contract provided a Deutsche Mark 0.75 (19-cent) increase per shift for all wage groups effective October 1, 1963, and another similar increase effective July 1, 1964. The salaries of white collar workers rose 6 percent, also payable in the same two equal steps. Shift-time for 85,000 surface workers was reduced from 8¼ to 8 hours. The employers estimate that the wage and salary increases, together with the wage group and worktime adjustments, will cost about $87 million annually.

Coke.—Coal-mining companies continued to produce considerably more coke than steel companies. During 1959–63 coal producers' coke output totaled 181,462,000 tons compared with 36,086,000 tons produced by steel companies. The steel industry in 1963 used 17,062,000 tons of coke compared with their production of 6,682,000 tons, indicating a substantial coke sale by the coal industry. Production of coke has declined since 1960; in 1963 total coke output was about 3 million tons less than in 1960. The decline presumably was due to declining coke consumption per unit of steel produced and declining consumption for household space heating. Disposal of coke produced by the coal companies and imported coke (304,402 tons) totaled 36,730,382 tons. Important recipients of this coke were the iron and steel industry (11,915,532 tons), household and small consumers (7,701,969 tons), other industries (3,684,940 tons), and exports and shipments to West Berlin and East Germany (12,526,857 tons).

At the beginning of 1963 there were 58 coking plants with a total of 580 batteries and 9,008 cells, excluding coke oven plants operated by steel companies.

Lignite (Braunkohle).—In 1963, 85 percent of the lignite was produced in the Rhineland where 95 percent of the reserves are located. In Rhineland one firm alone produced about 96 percent of the area's output in large open pit operations using bucket-wheel excavation. The bulk of the brown coal is used for power generation and briquetting.

TABLE 33.—Production of lignite, lignite briquets, and pech in 1963, by areas

(Thousand metric tons)

Commodity	Rhineland	Lower Saxony (Helmstedt)	Hessen	Bavaria	Total

Per working day	47.0	5.0	----	0.6	52.6

Source: Zahlen zur Kohlenwirtschaft, volume 63, February 1964.

All the so-called pech coal was produced in Penzberg, Bavaria. Approximately 40,000 to 50,000 tons of this formerly was used in U.S. Army installations in Bavaria, but in 1963 these requirements were supplied from U.S. sources.

Brown coal does not loom so large in trade, but brown coal briquet imports from East Germany are significant in meeting household and industrial needs of West Germany and West Berlin.

Coal Byproducts and Coke Oven Gas.—In line with the declining output of coke, production of coke oven gas and other byproducts of coke ovens continued to decline modestly from the peak level of 1960.

Petroleum.—In 1963 the Federal Republic of Germany was the largest producer of crude oil in Western Europe. Its 1963 output of 7,382,700 tons (53,325,000 barrels) was 0.6 percent of the world total and 15.5 percent of West German refinery throughput. Petroleum reserves at the start of 1963 were 81,778,000 tons (590,682,000 barrels) proved and 106,225,000 tons (767,263,000 barrels) probable. Natural gas reserves were 1,278 billion cubic feet proved and 424 billion probable. Important discoveries, notably in the Barrien field near Bremen, may have increased the gas reserves.

Production of crude and consumption of petroleum products and refinery throughput set new records in 1963. Net imports grossed almost US$1 billion. Three new refineries came into operation, adding 6,300,000 tons (45,505,000 barrels) annually to the country's refining capacity. The new Caltex refinery is at Raunhein; the other two plants and the four refineries under construction are in the south, shifting the refining center from the north to the south.

Petroleum's share of the West German energy market increased at the expense of coal to 32.6 percent, compared with 29.4 percent in 1962. Competition within the industry remained sharp and owing to the new refineries, prices of petroleum products in Bavaria declined.

TABLE 37.—Producing oilfields

Field	Producing horizons	Estimated total reserves Jan. 1, 1963 (thousand tons)	Structure
North German basin:			
Emsland—west of Ems River	Upper Jurassic to Lower Cretaceous.	39,820	Anticlines.
Weser-Ems—between Weser and Ems Rivers.	Middle Jurassic to Lower Cretaceous.	27,853	Salt domes and stratigraphic traps.
Hannover—between Elbe and Weser Rivers.	Upper Triassic to Upper Cretaceous.	25,526	Fault traps and salt domes.
Schleswig-Holstein—north of Elbe River.	Middle Jurassic and Lower and Upper Cretaceous.	14,765	Salt domes.
Upper Rhine Valley	Eocene to Pliocene	3,471	Fault trap.
Bavaria (Alpine Foreland)	do	1,803	Stratigraphic traps.

A law abolishing import duties on crude effective January 1, 1964, was passed; it also provided for a corresponding increase in the level of internal taxation on petroleum products. Federal excise tax on petroleum products yielded $1,034 million in 1963 compared with $945 million in 1962 and $831 million in 1961. Revenues of the Federal Government for all oil duties and taxes in 1962 have been estimated at $1.25 billion.

Production, Consumption, and Trade.—Contribution of the North German basin to the total 1963 output was 93 percent; the remainder was almost equally divided between the Upper Rhine Valley and the Alpine Foreland fields of Bavaria. The area between the Elbe and Weser, with 32 percent of total production, ranked first among the producing areas.

TABLE 38.—Petroleum production by areas, 1959–63

(Metric tons, unless otherwise specified)

Area	1959	1960	1961	1962	1963
North German basin:					
North of Elbe (Schleswig-Holstein)	449,781	490,297	592,537	743,909	800,024
Between Elbe and Weser (Hannover)	1,865,437	1,999,651	2,125,131	2,209,409	2,378,738
Between Weser and Ems	1,142,960	1,330,990	1,582,087	1,624,141	1,709,720
West of Ems (Emsland)	1,352,697	1,356,243	1,540,997	1,772,276	1,982,505
Upper Rhine Valley	178,140	212,984	217,263	235,408	250,246
Alpine Foreland (Bavaria)	113,743	139,727	146,448	191,210	261,467
Total	5,102,758	5,529,892	6,204,463	6,776,353	7,382,700
Rate of increase, percent	15	8	12	9	9

Of the 115 fields which produced in 1963, 60 had a production exceeding 10,000 tons (approximately 70,000 barrels). Of the 60 fields, 43 were in the North German basin. Ruhle in Emsland was the largest field, followed by Hankensbuettel in the Hannover area and Georgdorf. These three fields produced 11, 8, and 7 percent of the country's output respectively. Nearly 77 percent of the domestic crude production comes from German-controlled companies. Production by companies in 1962 follows: Gewerkschaft Elwerath 1,505,000 tons; Deutsche Erdoel A. G. 1,345,000 tons; Wintershall A. G. 1,091,000 tons; Preussag 710,000 tons; Deutsche Schachtbau- und Tiefbohr G.m.b.H. 393,000 tons; C. Deilmann Bergbau G.m.b.H. 247,000 tons; and others 63,000 tons. Mobil Oil A. G. in Deutschland through Celle, its local subsidiary, was West Germany's largest foreign-owned crude producer, followed by Brigitta, a joint subsidiary of Shell and Esso. These companies in 1962 produced 1,013,000 and 410,000 tons, respectively.

While refinery throughput has shown a continuous increase during the last decade, rate of increase was only 19.2 percent in 1963 and 12.9 percent in 1962, compared with 32 percent in 1960 and 43.5 percent in 1959. There has been a significant change in the relative shares of the various refinery products in total output.

In 1962 West Germany was the third largest free world consumer of petroleum products, after the United States and United Kingdom, and it may have had the same rank in 1963. Motor vehicle registration in 1963 increased to 10,830,419, 4.9 percent more than in 1962. Despite increased road transportation a shift has taken place starting in 1955, in the relative position of heating oil (light and heavy fuel oil) and

Digitized by Google

automotive fuels in total consumption; heating oil is gaining in share of total consumption. During 1959–63 the rate of annual increase for heating oil was 15 to 35 percent, compared with 12 to 17 percent for motor gasoline and 9 to 11 percent for diesel oil. Diesel oil, besides being diesel automotive fuel, is also increasingly used for commercial heating.

West Berlin did not produce any crude or refined products, and consumption requirements were met entirely from West Germany refineries.

TABLE 39.—Relative shares of production and consumption [1] of refinery products, 1955 and 1959–63

(Percent)

	1955	1959	1960	1961	1962	1963
Production:						
Automotive fuels	57	43	37	36	36	37

Other products	24	17	15	14	15	13
Consumption:						
Automotive fuels	59	41	38	35	32	29
Heating oil	22	46	50	54	57	58
Other products	19	13	12	11	12	13

[1] Excluding refinery consumption.

With increasing refinery capacity, crude imports have increased every year since 1948, except for a small decline in 1952; 1963 import was 2.4 times that of 1959. Although the absolute quantity imported from the Near East has increased, there has been a decline in percentage of imports from this area. Of the 1963 imports of 40,438,500 tons, the Near East supplied 23,526,200 tons, or 58 percent, compared with

TABLE 40.—Consumption of petroleum products

(Metric tons)

Commodity	1959	1960	1961	1962	1963
Domestic:

70 to 81 percent during 1959–62. Other sources of crude in 1963 were Algeria, which contributed 6,594,700 tons (16 percent) and Venezuela, 4,278,300 tons (10.6 percent).

Imports of refined products, principally distillate and residual fuel oils, attained their maximum in 1962. Refined products are imported substantially by the refining companies.

In the last several years Switzerland has been an important export destination for German refinery products but the importance of this country is expected to diminish when its first refinery, being built at Aigle, comes into operation. Much of the trade with the Netherlands and United Kingdom is essentially exchange of products within individual companies.

Transportation, Distribution, and Marketing.—According to industry sources, West Germany's tanker fleet at the end of 1963 consisted of 91 units (including tank lighters) totaling 1,285,369 tons deadweight. Esso Tankschiff Reederei G.m.b.H. (Standard Oil of New Jersey), with 14 units totaling 503,987 tons deadweight, controls more than a third of the total tonnage of the West German tanker fleet. Of the North German ports, Wilhelmshaven can berth 60,000-ton-deadweight tankers, Unterweser 50,000-ton tankers, and Hamburg 30,000- to 40,000-ton tankers. It is planned to increase the maximum tonnage that Hamburg can berth to 50,000 tons by deepening the Elbe River.

Rail, highway, and canal haulage facilities have been unable to handle the very large volumes of crude imports, especially to the inland refineries. As a result, a fairly extensive pipeline construction program has been underway. Two pipelines from North Sea ports and a third from Lavera near Marseilles on the Mediterranean have been built to carry crude to inland refineries. Another pipeline from Genoa is to be completed in 1964. Gathering lines, totaling 1,000 kilometers, connect the oilfields to various refineries.

Crude oil from overseas destined for West German refineries was off-loaded at the following ports (percentage of total shown in parentheses): Wilhelmshaven (38 percent), Hamburg-Brunsbuettelkoog (24 percent), Rotterdam (21 percent), Marseilles (11 percent), Bremen (3 percent), and Emden (3 percent). Of the crude oil imported into West Germany, 68.4 percent was delivered from the port to refinery by pipeline. The remainder was either off-loaded directly from ocean carrier to refinery or delivered by inland tankers or tank cars.

TABLE 41.—Transportation of crude oil and products by various means in 1962

(Metric tons)

Transportation means	Crude oil	Automotive fuel oil and heating oil	Other products	Total
Railroads	3,911,600	11,310,800	3,045,400	18,267,800

Deliveries of crude oil to West German refineries by long-distance pipelines increased to 28.2 million metric tons in 1963. Of this total, 15.51 million tons were carried by the North West pipeline (Wilhelmshaven to the Ruhr), 7.87 million tons by the Rotterdam-Rhine pipeline, and 4.8 million tons by the South European pipeline (Marseilles to Karlsruhe).

Refinery products have been distributed almost entirely by inland waterways, railroads, and highways. Although river barges at times transport crude, they have been far more significant in transportation of products. In 1963, there were about 800 of these barges with a total capacity of approximately 500,000 tons. The railroads distribute oil products to consumers who are not directly on the waterways and to large consumers who have their own sidings. As of June 30, 1963, there were 29,421 privately owned railroad tankers for oil distribution.

It is believed that the refinery product pipeline from Esso's Cologne refinery to several industrial areas around Essen and Dusseldorf is the country's only such line. Construction of refineries in various parts of the country and their nearness to consumers obviate the need

TABLE 42.—Major crude pipelines

Pipeline	Diameter (inches)	Length (kilometers)	Annual throughput capacity [1] (million tons)	Tonnage transported in 1962 (million)	Remarks
International:					
Rotterdam-Venlo-Wesel-Wesseling. [2]	24	303	8.5/20	7.0	Completed in 1960; supplies the Gelsenkirchen and Godorf refineries and, through the Wesseling-Kelsterbach line, the Caltex refinery at Raunheim.
South European (Lavera-Karlsruhe).	34	806	13/30	.1	Supplies crude to the DEA/Scholven AG. and Esso AG. refineries at Karlsruhe and, through the Rhine-Danube pipeline, the Esso and Deutsche Shell AG. refineries at Ingolstadt.
Genoa-Ingolstadt [3]	----------	1,000	16/18	----------	Under construction by Ente Nazionale Idrocarburi to supply crude to its Ingolstadt refinery. At Ulm the line will divide into 2 branches, 1 to Ingolstadt and 1 to Heilbronn.
National:					
North West, (Wilhelmshaven-Cologne).	28	384	18/22	14.2	Completed in 1958. The capacity was increased from 15 to 18 million tons annually. Supplies refineries at Lingen, Dinslaken, Oberhausen, Duisburg, Cologne, Scholven, and Wesseling.
Rhine-Danube (Karlsruhe-Neustadt).	26	280	8/15	----------	Completed in November 1963, this is an extension of the South European pipeline which will supply crude to the Monheim refinery and the Esso and Shell refineries in Ingolstadt.
Karlsruhe-Mannheim	----------	66	2/5	----------	Extension of the South European pipeline.
Wesseling-Kelsterbach (near Frankfurt).	----------	150	2	----------	Extension of the line from Rotterdam to serve the Caltex refinery near Hoechst.

[1] 2d figure denotes alternate capacity.
[2] From Venlo on the West German-Netherlands frontier, the line divides. One line (45 kilometers long) goes to Wesel to join the 45-kilometer 16-inch Wessel-Gelsenkirchen pipeline, and another (103 kilometers long) goes to Wesseling.
[3] Extension of this line from Ingolstadt to Heilbronn is planned.

Digitized by Google

for distribution of products by pipeline, and in case of emergency products have been carried by crude pipelines.

Practically all West Berlin requirements were provided by barges. Several firms continued building new and expanding existing storage facilities in West Berlin. Completion of these will bring the total refinery products storage capacity to 500,000 cubic meters.

It is estimated that 80 percent of the gasoline and 20 percent of diesel oil sold were handled by service stations and that the remainder for each product was sold directly to the consumers. Nearly 80 percent of the heating oil has been sold through coal retailers and wholesalers. Six companies controlled approximately 70 percent of all gas stations. These companies and their number of stations follow: Aral A.G. 6,200; Deutsche Shell A.G. 5,250; Esso A.G. 5,220; BP Benzin und Petroleum A.G. 4,000; Deutsche Erdoel A.G. 3,500; and Deutsche Gasoline Nitag A.G. 3,200. At the end of 1963 there were about 38,820 gas stations in West Germany, of which about 3,000 were independent; the remainder had a special business relationship with the refining companies. The largest distributor of motor fuels in West Germany is Aral; Gelsenkirchner Bergwerks A.G. controls this firm through its own 47-percent direct share and by administering Mobil's 11-percent share. Aral has no domestic crude or refinery production and obtains all its supplies from German refining companies.

TABLE 43.—Petroleum refineries in operation at end of 1963

Company and refinery location	Throughput capacity	
	Thousand tons per year	Barrels per day (approximate)
BP Benzin-und Petroleum, A.G.:

Refineries.—Refinery throughput in 1963 was 47,188,072 tons.

Refinery capacity has increased continuously since 1956. At the end of 1963, 30 refineries were in operation with a total throughput capacity of 57.4 million tons; 4 refineries with 10.4 million tons capacity were under construction. Of the operating plants, 13 had individual capacities exceeding 2 million tons per year (76 percent of the total), and 7 had capacities of 1 to 2 million tons per year (21 percent of the total). In addition seven refineries aggregating 16 million tons' annual throughput were planned and refinery throughput was expected to reach 59.6 million tons in 1964.

In 1962, 57 percent of the capacity was in the Rhineland and 43 percent in North Germany. The refining capacity as of January 1, 1964 (including Esso Ingoldstadt), according to geographic regions, follows: Rhein-Ruhr 45 percent; South Germany 21.7 percent; Hamburg 13.9 percent; Niedersachsen 14.9 percent; Schleswig-Holstein 5.6 percent; and Bremen 2.4 percent. Nearly 31 percent of the refinery capacity is U.S.-owned.

Catalytic reforming 670,000; Hydrofining 950,000.	1964.
Erdoel-Raffinerie Ingolstadt (Ente Nazionale Idrocarburi, 100 percent): Ingolstadt.	2.0	Gasoline 24; turbofuel, diesel oil 10.5; light fuel oil 26; heavy fuel oil 36; refinery gas 3.5.	Catalytic reforming 400,000.	1964.

[1] 200,000 tons of bitumen and 240 million cubic meters of gas per year.
[2] 100,000 tons of bitumen and 180 million cubic meters of gas per year.
[3] 470 million cubic meters of gas per year.

Natural Gas.—Natural gas produced in Germany consists of unassociated gas and of associated or dissolved gas. In 1963 there were 33 gasfields with individual annual production exceeding 1,000,000 cubic meters—18 in the North German basin, 11 in Bavaria, and 4 in the Upper Rhine Valley. North Germany was the principal producing area, accounting for 80 percent of the 1963 output. Bavarian fields ranked next with 24 percent. Rehden, the largest field, accounted for 23 percent of the country's total output. Prospects for the future yield of the Bierum structure, which is bisected by the German-Netherlands border, led Gewerkschaft Brigitta to announce in September 1963 its plans to build a pipeline to deliver gas from this field to Hamburg.

Digitized by Google

Municipal gas supply systems are the major users of natural gas, accounting for about 50 percent of consumption, followed by the chemical and iron and steel industries. Petrochemical plants are the principal users of refinery gases.

Much of the gas is transported in public utility lines which distribute it mixed with coke oven gas. At the beginning of 1963 there were probably about 900 kilometers of pipeline exclusively for natural gas. An 80-kilometer line built in 1962 connected the Bentheim gasfield to Dorsten; the latter is the largest coke oven producing center of Germany and is located on the Ruhrgas network. The natural gas, after dilution and processing, is pumped in the network and excess gas is sent directly to Duisburg. A second line completed in 1962 connected Rehden field to Landesbergen. Gasversorgung Sueddeutschland G.m.b.H. (South German Gas Supply Co.) is building, or has completed, a 240-kilometer gas pipeline from Mannheim to Freiberg and a 130-kilometer line from Mannheim to Ulm.

Gasversorgung Sueddeutschland G.m.b.H., Stuttgart; Gas-Union G.m.b.H., Frankfurt; and Ruhrgas, Essen (the latter handling mainly coke oven gas), which are engaged in gas transportation, reportedly agreed to cooperate in exchanging gas supply and to coordinate building of gathering pipeline systems in the country. In mid-1964 Gasversorgung Suddeutschland and Gas-Union will start to take increasing quantities of coke oven gas for the areas they are serving. In case of need this operation was to start in the winter of 1963–64.

Exploration and Development Activities.—Discovery of the Groningen gasfield in the Netherlands and the deeper producing formations in the Rehden gasfield in West Germany stimulated interest in possible new concessions in the North Sea Continental Shelf. In April 1963 the Oberbergamt Clausthal, on behalf of the four coastal States, granted a concession to a consortium consisting of Preussische Bergwerks- und Huetten A.G. (Preussag), Amoco Hanseatic, C. Dielmann Bergbau G.m.b.H., Deutsche Erdoel A.G., Deutsche Schachtbau- und Tiefbohrgesellschaft G.m.b.H., Gewerkschaft Elwerath, Gelsenkirchener Bergwerks A.G., Gewerkschaft Brigitta (a subsidiary of Esso and Shell), and Wintershall A.G. were preparing to explore and exploit within the German portion of the North Sea Continental Shelf outside the 3-mile limit. The consortium was to start drilling the first exploration well and was scheduled to spud a well in April 1964 on a Dielmann concession of 190,000 acres north of the East Frisian Island of Borkum.

The Continental Oil Co. acquired the exploration rights of Niedersachsen G.m.b.H., Hannover, in Lower Saxony (transfer of rights to take place January 2, 1964) and three exploration rights in its own name in the same State.

Development drilling declined in 1963 because of the expected removal of import duties on crude and uncertainty about the protection of the competitive position of domestic crude. Well drilling totaled 434,000 meters in 1963, compared with 504,000 meters in 1962. The 1963 total comprised 125,000 meters of exploration wells, 89,000 meters of extension, 200,000 meters of production, and 20,000 meters of service wells.

Legislation on Petroleum and Natural Gas.—In accordance with the mineral oil protocol of the EEC Treaty the Government abolished, starting on January 1, 1964, customs duties amounting to $20 per ton on crude imports. These duties are replaced by correspondingly higher internal taxes. To help the domestic producers adjust to the new conditions, the law provides a 6-year subsidy on a decreasing scale (from US$12.50 to US$5 per metric ton) for domestic crude and low-interest loans for oil exploration by German firms outside the Common Market countries. The sums assigned for these purposes are US$310 million for subsidy and US$200 million for credit. A ceiling of US$77.5 million was set for 1964; production in excess of 6.2 million tons will not be subsidized. The law also abolished preferential treatment given to the three tar-hydrogenation plants which produce a substance similar to residual fuel oil.

With regard to the exploration and exploitation of oil and gas resources in the area of the North Sea, as of the end of 1963, West Germany had not ratified the Geneva Convention on the Continental Shelf of April 29, 1958. In a proclamation of January 20, 1964, the Government stated that it would submit to the legislative bodies the draft of a law approving the Convention. To eliminate legal uncertainties before Germany ratifies the Convention and it comes into force, the Government considers the Federal Republic to have exclusive sovereign rights in exploring and exploiting the natural resources of the seabed and the subsoil of the submarine areas adjacent to the German coast but outside the area of the German territorial sea, to a depth of 200 meters or, beyond that limit, to where the depth of the superjacent waters admits of the exploitation of the natural resources of the areas.

The Mineral Industry of Greece

By J. M. West[1]

THE MINERALS sector of the Greek economy contributed an estimated 3.5 percent to the approximate US$3.5 billion gross national product in 1963. Some 20,000 persons were employed in the mining industry out of a total population of 8.5 million. Largest employment was in lignite followed by stone, magnesite, and bauxite mining. The mine production index, reported by the National Statistical Service, suffered a small setback in 1963 from the previous year as output of most minerals (with the notable exception of coal) fell off. However, other indices went up in 1963: coal-petroleum 13.2 percent—largely due to coal; nonmetals 13.1 percent—because of cement; and basic metals 13.7 percent—because of new pig iron and steel operations. Greece's share of world production was about 3 percent each for bauxite and barite, 2 percent for magnesite and chromite, and 0.5 percent each for lead and zinc.

Lignite which was important domestically, providing over half of the country's electrical power, came into use during 1963 for manufacturing nitrogenous fertilizers. Greece, with one of Europe's lowest electric consumption rates—318 kilowatt-hours per capita in 1963—was deficient in power and striving to expand its generating facilities. Coal output had more than doubled since 1959. Most mine products, except coal, went to export markets. Cement and steel made significant contributions to national income. The country was dependent on foreign sources for crude oil; its single refinery fell somewhat short of satisfying requirements for refined petroleum products.

Planning continued on the ESSO-T. Pappas (U.S. investment group) US$110-million-plus complex in the Thessaloniki area which will include an oil refinery, ammonia plant, petrochemical works, and steel mill. Construction was due to start on some components in 1964. At Ptolemais, coal mining capacity was being expanded and a US$70-million government-owned nitrogenous fertilizer plant was completed. Other fertilizer plants were under construction, one near Karvali (phosphates). Also in 1963 Halyvourgiki started up the country's first blast furnace near Athens; equipment was being brought in to Larymna mines, Euboea, to produce nickel and steel; aluminum smelter construction started on the Gulf of Corinth; several cement plants were adding capacity; and the Government was looking for investors to develop the Kozani asbestos deposits.

GOVERNMENT POLICIES AND PROGRAMS

The need to increase investment in industrial enterprises was probably the foremost economic problem facing the Greek Government. Heavy reliance had to be placed on foreign investors because of hesitancy of local entrepreneurs. Greece had favorable laws regarding investment and repatriation of money, and the Government was especially eager to attract U.S. capital. The Greek 5-year plan 1960–64, aimed primarily at industrialization, gave particular attention to mining activity and development of related basic industries. The process was expected to accelerate after the country's entry, as an associate member, into the European Common Market on November 1, 1962. Agreements signed did not provide for trade in coal, coke, iron ore, and steel mill products, since these were controlled by the European Coal and Steel Community (ECSC). Entry into ECSC was under discussion in 1963.

In the area of public investment one of the chief agencies was the Industrial Development Corporation (IDC), essentially government controlled and 45 percent owned by the Greek State. The IDC was active in encouraging exploitation of the country's minerals and promoting industrial development. Among IDC activities in 1962–63 were prospecting for molybdenum, antimony, and manganese deposits; investigations of mining properties under option, including Chalkidiki, Cavala iron, and Rodopi mines; exploration of Kirki zinc mines; studies of calamine ore, bentonite, and perlite potentials; iron ore beneficiation; and a feasibility study for a zinc plant.

PRODUCTION

Cement and lignite coal in nearly equal shares contributed about half of Greece's estimated US$100 million in mineral production value during 1963; steel ran a poor third in importance. Among minerals produced bauxite was foremost followed by lead-zinc ores, sea salt, magnesite, iron ore, and chromite, in about that order. Of the coal, which was mined mostly in the Ptolemais area, about 90 percent was used for electric power generation. Cement production could hardly keep up with demand although output boomed ahead an estimated 20 percent over 1962. Steel was produced from scrap, the main product being concrete reinforcing bars. Chromite output declined because of poor market conditions, with only two mines reported operating. An upward trend in bauxite production was halted, at least temporarily, by export limitation as efforts were made to save developed supplies for soon-to-start domestic aluminum smelting. Output dropped 10 percent from 1962 despite high world demand. Crude petroleum, all imported (Greece having no production), was refined at Aspropyrgos. Throughput was slightly higher than in 1962. Phosphate fertilizers were manufactured from imported phosphate rock by Hellenic Chemical Products and Fertilizers Co. at Drapetsona. Production of barite and bentonite rose in 1963.

TRADE

Greece traded largely with the European Economic Community; also, a fair amount with European Communist countries. Crude oil came mainly from Saudi Arabia, phosphate rock from Morocco, and sulfur from the United States. Metal and mineral imports in 1962, the latest year for which data were available, totaled roughly US$120 million, about 6 times the value of mineral exports. Crude oil and petroleum products comprised about 40 percent of the mineral import value, the crude being slightly over half of this. Steel accounted for about 40 percent also. Imported hard coals were used by the railroads and coke by steel industry. Bauxite, the most important mineral export, comprised 28 percent of the mineral and metal shipment value in 1962, with magnesite and its calcined products second at 20 percent.

COMMODITY REVIEW

METALS

Aluminum.—Greece, with a large reserve of bauxite but relatively expensive electrical power for smelting, was on its way to becoming a primary aluminum producer by 1965–66. Foundation work began in April 1963 on a planned US$113 million project at Paralia, near Distomon, northwest of Athens, to produce initially 200,000 tons of alumina and 62,500 tons of aluminum metal annually utilizing 450,000 tons per year of bauxite to be obtained mainly from the nearby Eleusis and Parnassos deposits. The company, Aluminion Ellados (The Aluminum Co. of Greece) was formed by Péchiney, of France, with controlling share; Industrial Development Corp. (I.D.C.), held

Digitized by Google

partly by the Greek State; Reynolds International, a subsidiary of U.S.-based Reynolds Metals Co.; and by several other investors. A subsidiary, Bauxitai Parnassou, was developing the bauxite deposits. Electric power for smelting was due late in 1965 from the Kremasta hydroelectric station being built by Kaiser Engineering (associated with the U.S. firm, Kaiser Aluminum Co.) on the Acheloos River, in western Greece. The new industry would consume one-fourth of the country's electrical output when fully operating.

A combine of Péchiney and Ugine (France) and Viochalco (Greece) interests was setting up operations to make semifinished aluminum and foil products. Kaiser was also considering aluminum fabrication in Greece using metal from the new smelter. Domestic aluminum consumption was 6,000 to 7,000 tons in 1963. Of the forthcoming output over 50,000 tons of metal and 80,000 tons of alumina was expected to be available for export. West Europe, because of rising metal consumption and Greece's Common Market ties, would be a prime outlet.

Bauxite.—Bauxite production was about 10 percent lower than in 1962. Most of the ore was exported; West Germany and the U.S.S.R. had been the largest purchasers in 1962. Under terms of a 1960 agreement between the Greek Government and the Péchiney group (Aluminum Co. of Greece) to assure the company an adequate ore supply, the Greek Minister of Commerce placed a ceiling of 1 million tons on 1963 exports of bauxite. The ceiling, renewable annually for 30 years in absence of intervening mutual agreements, was imposed after negotiations between the Péchiney group and major Greek bauxite mine operators had deadlocked over proposals to supply the group with bauxite at the formulated price. The Bank of Greece was instructed to issue licenses to individual bauxite exporters for half of their 1962 allotments pending official enactment of new export quotas. Operators pressed for a higher ceiling.

Greek reserves of bauxite have been estimated at 12 million tons proven plus 50–60 million tons of possible ore, mainly located south of Mt. Parnassos but with some on the Island of Euboea and the Chalkidiki Peninsula. The Greek Government was obliged by its contractual agreements to limit bauxite exports until smelter supplies totaling 30 million tons of ore could be established. One company felt it should not be subject to export restriction arguing that its mine came into operation after the contracts were signed.

Chromite.—Crude ore production at the Xerolivado mine, the chief producer, was 46,464 tons compared with 51,406 tons in 1962; 11,444 tons of metallurgical grade concentrate was produced in 1963 and at yearend 18-month stock remained unsold. Although the Domokos mine was closed in October 1961, the mill continued to operate through August 1962 on stockpiled ore, producing 4,424 tons of submetallurgical grade concentrate during the 8 months before shutdown. Refractory ore was produced at the Tsagli mine. Competition with low-priced Russian chromite was a serious problem. In view of this, the Industrial Development Corp. (Greek combine) considered establishing domestic chrome-steel and refractory manufacturing operations.

Copper.—Consumption of copper, based on imports, was estimated at 7,000 tons in 1962 and probably slightly higher in 1963. There was

Digitized by Google

no domestic production. Copper deposits in the Skouries area, Chalkidiki Peninsula, were being explored jointly by Nippon Mining Co. (Japan) and Central Chalkidiki Mines (Greece), the Greek company holding mineral rights to over 30,000 acres of property. Studies so far indicated the ore to average 1.5 percent copper. The Japanese firm reportedly was planning a US$3 million flotation plant depending on outcome of exploration.

Iron Ore.—Output of iron ore dropped sharply in 1963 from that in 1962. During 1962 ore was exported mainly to Austria and West Germany. At the start of 1963 the Hondrodimos mine on the Island of Thassos was idle with large stocks on hand. A survey of Thassos deposits by the French Bureau de Recherches Géologiques et Miniéres indicated iron ore on the order of 70 million tons. Generally these deposits run about 30 percent iron. Halyvourgiki applied for concession to mine government-owned deposits on Thassos Island and negotiated with French leaseholders of idle mines on Serifos Island for short term ore supply. ESSO-Pappas also was interested in establishing ore sources.

Iron and Steel.—Pig iron was produced in Greece for the first time, when in mid-1963 one of a pair of blast furnaces built by Halyvourgiki, S.A., at Elefsis, near Athens, was blown in.[2] The 500,000-ton British- and West German-equipped plant featured oil injection to blast furnaces and LD steelmaking. Production was limited initially as complaints were voiced that imported steel, especially from the Soviet bloc, was being dumped below fair price on the local market. The Greek Government followed up by imposing an antidumping duty on reinforcing bars (the new plant's chief product) and investigated other charges. However, no fines were collected. The company also requested relief from export duties and taxes.

U.S. investors, ESSO and T. Pappas, with others possibly joining, continued plans and negotiations to establish an integrated steel operation as part of its Thessaloniki steel-petrochemical complex. The project taking shape would call for US$25–$30 million in steelmaking and US$50–$55 million in rolling mill facilities. Capacity was planned for 270,000 ingot tons, initially, expanding to 1 million tons per year. Salzgitter, of West Germany, was originally named to supply the plant but discussions were being held in late 1963 with Republic Steel Corp. (United States) over installing a used U.S. mill and possibly obtaining pig iron from the Halyvourgiki works. Negotiations also were carried on with M. W. Kellogg Co. (United States) for erection of a sponge iron plant.

Greek consumption of steel, estimated at 485,000 tons in 1962, was expected to climb to 600,000 tons in 1964 and 1,250,000 tons in 1971. A big factor in such a rise would be shipbuilding and its increased plate requirements. Over half of the steel consumed in 1962 was imported but, with the new facilities, Greece was expected soon to fill its own requirements.

Lead and Zinc.—Lead was smelted and zinc ore was concentrated for export by Mines de Laurium, a French company, at its deposit near Laurium, southeast of Athens. Lead metal output was 1,965 tons in

[2] Goatman, Ian W. Halivorgiki—Greece's First Integrated Steelworks. Steel and Coal (London), Nov. 15, 1963, pp. 958–960.

Digitized by Google

the first half of 1963. The company produced about 5,500 tons of lead concentrate and 7,800 tons of zinc concentrate in 1962, accounting for roughly one-fourth of the country's output of each. Also, Mediterranean Mines was active at Laurium and Hellenic Chemical Products and Fertilizers Co., Ltd., ran a concentrator at Kassandra.

Results of an IDC feasibility study favored construction of a US$17-million zinc smelter processing domestic ore and producing 15,000 tons of zinc annually. Such a refinery, situated in northern Greece, would draw mainly from Lavrion and Kassandra deposits where proven reserves are adequate for at least 10 years. Its establishment would encourage prospecting on nearby Greek islands. The IDC gave priority to the smelter project and commenced surveys of zinc mines in the Circe area, near Alexandroupolis. A byproduct sulfuric acid plant of 25,000 to 30,000 tons capacity was being planned.

Nickel.—Hellenic Chemical Products and Fertilizers Company, Ltd., through its Larymna Mines Co., acquired control of nickel-iron deposits on the Island of Euboea and signed agreements with Societe Le Nickel (France) forming Societe Miniére et Metallurgique Larco to exploit the Larymna deposits and produce nickel and steel in Greece. Only small tonnages of the ores had been mined previously. A US$15-million plant installation was expected to be in operation by mid-1965 with capacity of 4,000 tons of electrolytic nickel and 80,000 to 100,000 tons of steel annually.

NONMETALS

Asbestos.—An 8-year concession held by Kennecott Copper Corp. to explore asbestos deposits in the Kozani area expired at the end of 1963. The company reportedly spent about US$1.5 million for exploration and research but had not satisfied government expectations. Commercial production was not achieved; however, development appeared certain to continue as Copper Range Co., a U.S. firm, and other companies showed interest.

Cement.—Consumption in 1963 was estimated at 2.2 million tons compared with 1.8 million in 1962. Besides gray cement, about 20,000 tons of white cement was produced. Loans totaling US$1.7 million were approved to expand General Cement Co. plants at Volos and Piraeus. American Cement Co. (United States) was interested in entering the Greek cement industry with a plant to be built at Patras, and Atlas Cement Co. (Greece) planned a cement plant at Elefsis. Titan Cement Co. studied the problem of using Ptolemais lignite at its Thessaloniki plant but might continue with oil since prices were lowered in early 1963. The 200,000-ton plant, opened in 1962, was being expanded to 600,000 tons by 1964–65. Chalkis Cement Co. planned to add a kiln in 1964 raising capacity to about 500,000 tons per year.

Magnesite.—Greece, a minor producer and insignificant consumer of magnesite, exported in 1963 a total of 123,524 tons, 101,079 tons calcined and the rest crude. The calcined product went mainly to the United States (29,359 tons), The Netherlands (28,354 tons), and West Germany (22,875 tons); Italy took about half of the crude. Several refractory plants were on order for the Island of Euboea. Magnesite, Ltd. (Greece), signed with NIKEX Hungarian Foreign Trading Co.

Digitized by Google

(Hungary) to supply a magnesite brick plant, and a British firm, General Refractories, Ltd., invested with the Greek Chemical Products and Fertilizer Co. in a US$3 million magnesite and chromite refractory plant to be built at Laurium.

Sulfur, Pyrites, and Fertilizers.—Sulphur Hellas, S.A., processed imported sulfur in its 35,000-ton grinding plant, completed in 1962. Pyrites, produced mostly by Hellenic Chemical Products and Fertilizers Co., Ltd., at Kassandra and Lavrion, were shipped to the company's Drapetsona fertilizer plant for making sulfuric acid. Kassandra pyrites also were exported to Italy and Austria. Hellenic was the only Greek fertilizer producer in 1962, with output totaling 268,652 tons.[3] However, several plants were under construction including a 312,000-ton nitrogenous fertilizer plant in the Ptolemais lignite area, making test runs in late 1963, and a 250,000-ton phosphate fertilizer plant at Karvali due to be operational in 1964. A 155-ton-per-day phosphoric acid plant was on order for the Karvali plant. Chemical Industries of Northern Greece was beginning on acid and fertilizer plants at Drapetsona and Tsayezi, and a 105,000-ton ammonia plant was planned in connection with a new petroleum refinery (ESSO, Pappas, and others) near Thessaloniki. Such large-scale expansion was destined to provide several times the current Greek consumption of fertilizers and leave large tonnages for export.[4]

MINERAL FUELS

Coal.—Greek production of lignite in 1963 was 29 percent greater than in 1962. The Ptolemais region, near Kozani, with a reserve estimated at 450 million tons, was the most important source of coal, providing about 70 percent of all production. Other sources included Aliveri and Megalopolis area mines.

Work proceeded on installing three new excavators at Ptolemais in 1963 to boost output capacity from 1.8 to 4.0 million tons. The increase was to supply a local nitrogen fertilizer plant just completed, which can consume 1.0 million to 1.2 million tons per year of coal, and to fuel a third unit at the Ptolemais thermal power station. A contract was let for the 115,000-kilowatt unit to a Swiss firm, Brown Boveri, for delivery in late 1965. This would raise Ptolemais generating capacity to 320,000 kilowatts. Preliminary studies were being pressed by the Public Power Corp. on a proposed 250,000-kilowatt thermal plant at Megalopolis. Total capacity of existing thermal and hydroelectric facilities in Greece was placed at 695,000 kilowatts in 1963, with expansions underway scheduled to double this capacity by 1968–69.

Greek demand for coal was met mostly by domestic lignite production but some importation of hard coal and coke was necessary. Poland and the U.S.S.R. in 1962 supplied 77,643 and 32,365 tons, respectively, of hard coal; agreements with the U.S.S.R. called for coal and coke shipments to Greece totaling 62,000 tons in 1963 and 67,000 tons in 1964. Coal imports from the United States were 34,834 tons in 1962 after having fallen to nothing in 1960–61. Coke imports in 1962 totaled 31,310 tons, mainly from West Germany and Italy.

Digitized by Google

Petroleum.—Crude oil was imported and refined at the Aspropyrgos refinery, owned by the Greek State and operated under lease by a private corporation. In 1963 the refinery imported 1,842,000 tons of crude, processed 1,849,000 tons, and put out 1,824,000 tons of products. Production was 2.3 percent greater than in 1962. Crude imports in 1963 were divided, as follows: For the lessee, 1,068,000 tons from Saudi Arabia and 321,000 tons from Iran; for the government, 454,000 tons from the U.S.S.R.

A proposed US$24 million 2.5-million-ton-per-year refinery to be built by the ESSO–T. Pappas group at Salonica was marking time while negotiations continued with the Greek Government.

Petroleum exploration was disappointing; several projects were active in 1963. A drill hole by British Petroleum Exploration Co., (Greece), Ltd., at Klissoura struck a small flow of oil at 15,500 feet but the well was noncommercial. Undaunted, the company started a second hole about 15 miles to the northwest. Drilling by the Greek Institute for Geology and Sub-Surface Research and Institut Francais du Petrole at Anemorahi, Epirus, disclosed traces of oil before the hole was abandoned at 8,400 feet. A second hole was being tried in the Epirus area by the government and a French contractor, Forenco. The French firm, Safor, concluded drilling at Kataria, on the Island of Rhodes, apparently without success, and was investigating sites on Karpathos. Mediterranean Supply, S.p.A. (Italy) submitted a proposal to explore for oil north of Larissa.

The Mineral Industry of Hungary

By Roman V. Sondermayer [1] and K. P. Wang [2]

HUNGARY does not produce a great variety of mineral products, and few are of world consequence. Mineral consumption is much larger than production and requires substantial imports. Bauxite, primarily for export, is the only significant mineral product by world standards. The more prominent Hungarian minerals, with output in percentages of the 1963 world totals, were roughly as follows: Bauxite, nearly 5 percent; and aluminum, cement, coal, pig iron, manganese ore, and steel ingots, 0.3 to 1.1 percent. Coal and petroleum and natural gas were of significance to the domestic economy.

Hungary's mineral and metal output value in 1963 was estimated to be 7 to 10 percent higher than in 1962. The contribution of the mineral industry to the 1963 gross national product was about 6 percent, and the 156,000 workers employed represented roughly one-eighth of the country's total labor force. Mineral trade, particularly imports, was vital. Mineral and metal imports consisted chiefly of raw materials, while exports were largely semimanufactured forms.

Major developments during 1963 included discovery of a new manganese deposit at Urkut, commencement of construction of a 300-ton-per-day manganese benefication plant at Eplezny, expansion of steel rolling capacity by 400,000 tons per year, completion of a new superphosphate plant at Szolnik, and commissioning of a large cement plant at Vac. A long-term agreement in late 1962 called for much larger future shipments of Hungarian alumina to the U.S.S.R. for metal reduction.

Coal was Hungary's principal source of energy in 1963, although natural gas became more important. Most coal deposits are low rank so that imports of high-rank coals, particularly coking coal, were indispensable. A new oilfield near Somogy Megue and several gasfields in the Transdanubian area reportedly were discovered during the year.

Development of mineral resources has been retarded by severe shortages of electric energy. The aluminum industry was the most severely affected, and was not able to fully utilize the newly completed reduction capacity. This situation led to the agreement covering increased exports of aluminum raw materials to the U.S.S.R. Rail transport also created difficulties. Since most mineral imports came from the U.S.S.R. where the railroad gage is different, rail cars with minerals had to be unloaded or the wheels had to be changed before proceeding. There was also a shortage of rail cars for transport of mineral products.

PRODUCTION

Mineral output of Hungary has shown on overall steady increase in recent years. In 1963, however, production of bauxite, the country's most important mineral product, was 8 percent lower than in 1962. A severe winter was the principal reason for the decline. Although 7 percent more iron ore was produced in 1963 than in 1962, output satisfied only one-fourth of requirements. Nonferrous base-metal production, though not reported, was undoubtedly far short of demand.

Hungary's most valuable mineral product continued to be coal, mostly brown coal. The overall coal output increased 7 percent over that of 1962. Increase in bituminous coal production was approximately 11 percent. The general rise in mineral output during 1963 should not obscure the fact that the mineral industry had the lowest rate of increase of any of the Hungarian economy.

TABLE 1.—Production of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:

Petroleum: Crude thousand tons	1,035.9	1,216.7	1,456.9	1,641	1,756

[1] In addition to reported commodities, Hungary is known to produce (figures where given represents 1963 production estimates) silver, 64,300 troy ounces; peat, 60,000 metric tons; arsenic, copper, gold, uranium, china clay, and diatomite.
[2] Data not available.

TRADE

As in previous years, Hungary was a net importer of most mineral raw materials, with bauxite and manganese ore as the major exceptions. The country depended heavily on foreign iron ore, high-rank coals, petroleum, and nonferrous base metals during 1963. As

Digitized by Google

a member of the Soviet Ekonomicheskoy Vzayimopomoshchi (SEV),[3] most of Hungary's trade in mineral and other commodities was with other (Communist) countries.

Hungary's most important trading partner was the U.S.S.R., which supplied the country with the bulk of its imports of raw materials and obtained small quantities of semimanufactures and finished products in return.

The long-range Hungarian-U.S.S.R. agreement to exchange alumina for aluminum means that much more aluminum metal will be available in Hungary for consumption in the future.

COMMODITY REVIEW

METALS

Bauxite and Aluminum.—The central Hungarian mountains continued to be the only major producing area for bauxite, alumina, and aluminum. Hungarian and Soviet experts made plans to expand two aluminum plants, one at Szekesfehervar and the other at Koebarya, each by 10,000 tons per year. The U.S.S.R. is expected to provide the technological knowledge and the financial means for these projects.

Work began on implementing the long-term agreement between the U.S.S.R. and Hungary to produce more bauxite and alumina in

Digitized by Google

Hungary and then send the additional alumina to the U.S.S.R. for reduction into aluminum. The plan by 1980 is to export 330,000 tons of alumina annually and receive 165,000 tons of aluminum ingot.

Iron and Steel.—Much work was done by the Hungarian Government in 1963 to improve the domestic iron-ore position; output was increased to 731,000 metric tons during the year. However, Hungary continued to rely on iron ore imports from the U.S.S.R., which amount to about 2 million tons annually. A new beneficiation plant was under construction near Miskolc in 1963, scheduled to supply iron concentrate to the Lenin Steel Works and the Ord Steel Works. A method was developed to separate siderite from barite for the Rudabanya deposit, yielding an initial concentrate containing 40 percent iron. Tests were conducted by the Hungarian Academy of Science to recover iron from tailings of alumina plants, with no economic results as yet.

Pig iron production was at about the same level as 1962, but steel ingot production increased slightly to about 2.4 million tons. The Cepel Iron and Steel Works was being reconstructed in 1963. The addition of 400,000 tons per year of new rolling-mill capacity portends greater output of steel products in the near future.

NONMETALS

Cement.—A new million-ton-per-year cement plant was brought into production in the fall of 1963 at Vac. Experts from East Germany assisted in the design and construction of the plant. Equipment also was supplied by that country. Thus, Hungary's cement capacity has been increased by about 50 percent to roughly 3 million tons.

Fertilizers.—The new sulfuric acid and superphosphate plant at Szolnik, completed in 1963, has an annual capacity of 120,000 tons of sulfuric acid and 200,000 tons of superphosphate. This plant was constructed with Soviet assistance.

MINERAL FUELS

Coal.—Production of all kinds of coal in Hungary increased slightly during 1963; about 70 percent was brown coal. In the Mecsek brown coal basin at Zobak in southern Hungary, mining of a 65-million-ton seam began in 1963. Ten years of work and 700 million forints (11.7 forints equal US$1) have gone into this project. The main shaft, already more than 600 meters deep, reportedly is to be extended. Production, which is expected to reach 1,500 tons daily by the end of 1964, presumably will be increased subsequently. Equipment includes underground conveyor belts to transport the coal to bunkers and automatically controlled hoisting skips.

New lignite deposits of some consequence were developed near Miskolc during 1963. An additional 150,000-ton-per-year briquetting unit was being constructed at the Hidas briquet plant.

Petroleum and Natural Gas.—Hungary's 1963 crude oil output of nearly 1.8 million tons came from 2 major fields, Levosy and Nagylenguel, and 42 very small fields. The potential of the newly discovered oilfield at Vizvar near the Yugoslav border has not yet been determined, but it reportedly produces both natural gas and oil.

Digitized by Google

The Szony oil refinery was enlarged during the year, and a new unit for regeneration of old lubricants was constructed. The Druzba pipeline was in operation in 1963, bringing in most of the imported oil, including crude oil from the U.S.S.R.

Large natural gas deposits were discovered in the Hungarian plains, and several pipelines were under construction to bring the gas to the consuming centers. These new gas finds are expected to give the coal industry stiff competition as an energy source.

The Mineral Industry of Ireland

By Walter C. Woodmansee [1]

RELATIVE to world supply and consumption, the metal and mineral economy of Ireland remained small. Its contribution to the country's national income was small compared with that of other industrial sectors. However, recent developments have stimulated the mineral industry and improved its domestic position. The most noteworthy of these developments is the 8-million-ton lead-zinc-silver deposit which was discovered in 1961 at Tynagh (County Galway). During 1963 this deposit was being prepared for large-scale mining operations, which are expected to begin in 1965. Foreign investment in this operation exceeded £10 million [2] through 1963, and the discovery has caused increased prospecting and exploration for base metals in other parts of the country. During 1963, about 60 companies and many individuals had mineral leases on 1,500 square miles in Ireland. Most of these companies are based or financed in Canada.

The only mineral commodity of world significance produced in Ireland in 1963 was sod and milled peat. Output has been 4 to 5 million tons annually, second only to that in the U.S.S.R. The mining and quarrying industries showed a marked expansion in 1962 (23 percent, based on value of product), owing principally to increased peat output and continuing high demand for construction materials. Gross value of mine and quarry products contributed about 2 percent of total industrial production in 1962. Small secondary metal production and the manufacturing of finished metal products, fertilizers, cement, brick, and other construction materials contributed 5 to 6 percent. During 1963 the growth rate in mining and quarrying was reduced to about 7 percent, because of lower demand.

Mining and quarrying activities employed approximately 10,000 people in 1963, mainly in peat mining and bog development, and secondly in stone and sand and gravel quarrying. The fertilizer, construction materials, and metal-working industries employed 14,000 to 15,000 people, most of whom were involved in metal fabrication.

GOVERNMENT POLICIES AND PROGRAMS

Mineral policy in Ireland was revised by the Petroleum and Other Minerals Development Bill of 1959, which encouraged foreign investment in Ireland by permitting foreign companies to hold exploration and mining leases granted by the State, which continues to reserve

[1] Foreign mineral specialist, Division of International Activities.
[2] One pound is equal to US$2.80.

Digitized by Google

mineral ownership. The new regulations provide for mineral licenses covering larger areas, up to 10 square miles, so that geophysical and geochemical methods are more effective. A company or individual is permitted to hold more than one license if prospecting and exploration are carried out satisfactorily. Tax legislation benefiting mining investment has been effective since 1956.

SOURCE MATERIAL

Much of the production data is derived from various nonofficial sources. The trade tables are based on "Trade Statistics of Ireland," compiled by Ireland's Central Statistics Office in Dublin.

PRODUCTION

Ireland's domestic metal production is limited to two firms—Irish Steel Holdings, Ltd., which makes open-hearth steel at Haulbowline (County Cork), and Metal Refiners, Ltd., which makes small quantities of secondary refined lead, high-grade zinc, and alloys at Clondalkin, 7 miles from Dublin.

There was no metal-mine production during 1963, owing to the closure in 1962 of the only active metal mine, the copper mine at Avoca (County Wicklow). However, renewed and successful activity in base-metal exploration, since 1962, indicates the likelihood of a return to copper-lead-zinc-silver mining, probably by 1965.

Among nonmetals, mine output of both barite and gypsum increased during 1963. New deposits of barite were under development. Quarry production of crushed rock, dimension stone, clay, and sand and gravel expanded steadily, owing to high demand in the building and construction industries. Cement output remained about on a par with that of 1962.

Coal and gasplant coke output remained relatively unchanged, but milled peat and peat briquet production expanded rapidly under the government's ambitious peat-bog development program.

Output of gasoline and fuel oils has steadily increased at the Whitegate oil refinery (County Cork) to a level which provides for nearly all the domestic requirements in these fuels.

Total	5,166	10,899	10,894	11,429	11,997

[1] Largely provisional or estimated.
[2] Small quantities of secondary lead and zinc, including alloys, are produced by one company, but output is not known.
[3] Data not available.
[4] Includes clinker.
[5] Totals are based on private sales and do not include large quantities of granite, limestone, sandstone, quartzite, sand and gravel, and other materials used by government agencies in maintenance of public roads.
[6] Final figure; supersedes figure given in commodity chapter, volume 1.
[7] Included with "Other nonmetals."
[8] Includes granite and other igneous rocks, quartz, calcite, roofing slate, pyrite (1959), and other sands, gravel, and clays.
[9] Figures for peat production apparently are based on marketed peat.
[10] Petroleum refinery production statistics are from World Petroleum Statistics, U.S. Bureau of Mines.

TRADE

Ireland's metals and minerals trade occupied only a small part of the country's total trade in 1962. Metal and mineral exports and reexports (principally petroleum products) totaled £8.6 million, 5 percent of the total value of £174 million for all exported goods. Estimated total value of metal and mineral imports in 1962, excluding manufactured products, was £48.1 million, 14 percent of the value of total imports (£273.7 million). These imports, far in excess of exports, were mainly in crude and refined petroleum (£18.8 million), coal (£8 million), and iron and steel (£8 million).

Ireland's limited needs in the ferrous and nonferrous metals continued to be met largely by imports of the metals, principally in the

Digitized by Google

semifabricated forms. The small output of nonferrous metal ores through 1962 was shipped abroad for processing.

Imports of all types of fertilizers, phosphate rock, and basic slag remained high, and the entire salt supply continued to be imported. Although petroleum derivatives are the most important products for export, large quantities of cement and raw construction materials also enter the export market.

Great Britain [3] remained the dominant source of imported anthracite and bituminous coals. Crude petroleum imports continued from the Middle East, and most petroleum refinery products came from Great Britain.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962 [1]
Metals:			
Copper:			
Ore and concentrate	28,474	15,190	West Germany 6,472; Belgium-Luxembourg 4,521; Sweden 4,196.
Scrap:			
Unalloyed	1,515	1,282	Spain 527; Netherlands 387; Great Britain 218.
Alloys	639	657	Mainly to Great Britain.
Iron and steel:			
Pyrite cinders	17,645	12,778	Great Britain 12,401.
Scrap	18,167	14,454	Italy 4,867; Spain 3,414.
Unwrought and value, pounds semimanufactures.	625,921	331,567	Mainly to Northern Ireland.
Lead, ore and concentrate	1,269	----	
Silver, bullion troy ounces	9,400	(2)	
Zinc, ore and concentrate	1,562	----	
Nonferrous metals, n.e.s.: [3]			
Scrap	1,817	3,138	Great Britain 836.
Unwrought and value, pounds semimanufactures.	514,243	418,919	Netherlands, Italy, Northern Ireland.
Nonmetals:			
Barite	8,555	----	
Cement	237,425	236,978	Great Britain 147,603; Northern Ireland 89,375.
Gypsum	83,449	86,630	(2).
Fertilizers	6,926	7,649	(2).
Stone, industrial	84,924	87,987	Great Britain 61,860; Northern Ireland 25,634.
Other	136,366	178.610	Great Britain 125,204.
Mineral fuels:			
Coal, coke	62,281	40,549	Norway 25,411; Netherlands 9,744.
Peat	41,633	38,179	Northern Ireland 22,805; Great Britain 15,230.
Peat moss	12,154	16,747	Mainly to Great Britain.
Petroleum refinery products: [4]			
Gasoline thousand 42-gallon barrels	35	62	All to Northern Ireland.
Distillate fuel oil do	1,001	988	Great Britain 964; Northern Ireland 24.
Residual fuel oil do	1,658	765	Great Britain 727; Northern Ireland 38.

[1] Great Britain and Northern Ireland, comprising the United Kingdom, are listed separately in Ireland trade publications.
[2] Data not available.
[3] Not elsewhere specified (n.e.s.).
[4] In 1961, reexports were (thousand barrels) aviation gasoline, 400; kerosine, 567; and lubricants, 18. In 1962, reexports, valued at £2,250,865, included (thousand barrels) aviation gasoline, 311; kerosine, 573; and lubricants, 17. Total value of metal and mineral reexports in 1962 was £2,663,180.

[3] Great Britain and Northern Ireland, comprising the United Kingdom, are listed separately in Ireland trade publications.

COMMODITY REVIEW

METALS

Aluminum.—Aluminum ingot has not been produced in Ireland, and all requirements for ingot, as well as partial requirements for semimanufactures, have been supplied entirely by imports. Consumption has increased with the recent establishment of several light metal industries. Aluminum foil and extruded products were made by Unidare, Ltd., at Finglas (County Dublin) during 1963. Irish Aluminium Company, Ltd., produced aluminum castings and finished products at Nenagh (County Tipperary).

Copper.—Mine production of copper was terminated with the closing of the Avoca mine (County Wicklow) of Saint Patrick Copper Mines in September 1962. The mine failure was attributed to excessive ore dilution, caused by caving, which resulted in ore grade of only 0.9 percent copper.

Smelter and refined copper have not been produced in Ireland. Concentrate output from previous years was shipped abroad for processing. Ireland's copper supply continued to be provided essentially by imported semimanufactured products.

Exploration for copper and renewed exploration activity for lead and zinc were relatively high during 1962–63. Prudential Petroleum Co. of Canada was drilling in the Killeen Mountains near Newport (County Tipperary), and Dennison Mines, Ltd., also of Canada, was involved in a drilling venture near Allihes (County Cork).

The important Tynagh lead-zinc-silver deposit, scheduled for production in 1965, contains 0.6 percent copper, which is recoverable as a byproduct. Copper also is associated with lead-zinc ores at Consolidated Mogul's mine at Silvermines (County Tipperary).

Iron and Steel.—Open-hearth steel capacity at the Irish Steel Holdings, Ltd., plant at Haulbowline (County Cork), the only steel plant in the country, was doubled to 80,000 tons with the addition of a new 70-ton open-hearth furnace and other improvements during 1962–63. Steel production has been based essentially on domestic scrap generation and imported pig iron, since there are no blast furnaces in the country. The steelplant produced light sections, mainly rounds and flats, and galvanized and corrugated sheets. Output of crude sheet and semimanufactures, however, has been only 20,000 to 30,000 tons per year, and 80 to 90 percent of domestic steel consumption has been based on imports.

Lead and Zinc.—Exploration and development of the Tynagh (County Galway) lead-zinc-silver deposit, discovered in 1961, continued through 1963. The property controller and operator is Northgate Exploration, Ltd., of Toronto, Canada. The deposit has been stripped to near-surface oxidized and residual ore, which will be mined by open pit, with first-stage production of 2,000 tons per day. A flotation mill was under construction at yearend. The concentrate produced at the mine site will be smelted in Belgium, West Germany, France, and the United Kingdom. Metallurgical companies in these countries are large investors in the mining operation.

Digitized by Google

Recent deep drilling by Irish Base Metals, Ltd., a subsidiary of Northgate, has delineated a large primary sulfide ore body below the oxidized zone, down to depths of a few hundred feet. Ore reserves are estimated as follows: Oxidized and residual ore, 4.5 million tons, 9.3 percent lead, 7.3 percent zinc, 0.6 percent copper, 3.5 ounces silver per ton; primary sulfide ore, 3.5 million tons, 4.8 percent lead, 4.3 percent zinc, 0.6 percent copper, 2 ounces silver per ton. Production is expected to be underway in 1965.

This significant discovery has encouraged widespread base-metal exploration in similar geologic terrain of other parts of the country. Zenmac Co., Canada, has discovered a lead-zinc-silver deposit at Loughrea (County Galway), near Tynagh. Consolidated Mogul Mines, Ltd., Toronto, Canada, acquired holdings of Silvermines Lead and Zinc Co., Ltd., of Nenagh (County Tipperary) at Silvermines (County Tipperary) and has initiated an exploration and development program in the vicinity of the old mines.

NONMETALS

Barite.—Small quantities of barite have been produced in Ireland for many years, both to meet limited domestic requirements and for the export market. Barite is associated with the lead and zinc sulfides at Silvermines. Magnet Cove Barium Corp. of the United States, which obtained a sublease on the property from Silvermines Lead and Zinc Company, Ltd., in 1962, has stripped a 700,000-ton deposit for open-pit mining. The company plans barite production of 50,000 tons per year. Discoveries of barite also have been reported in recent years in Counties Wicklow and Monaghan and also in the Benbulben Range (County Sligo).

Cement.—Irish cement output continued to provide an exportable surplus, in spite of the high level of domestic consumption caused by the continuing construction boom in Ireland. Cement, Ltd., an Irish company with close Danish associations, is by far the leading producer of cement in the country. Plants at Drogheda (County Louth) and Castlemungret (County Limerick) had a total annual capacity of approximately 900,000 tons of finished cement in 1963. Expansion plans for 1964–65 call for two new kilns and annual capacity of 1.2 million tons. Cement, Ltd., is one of the largest and fastest growing companies in Ireland. Total employment was approximately 1,000 in 1963.

Fertilizers.—Consumption of fertilizers has expanded rapidly because of government-encouraged efforts to improve crop and grazing lands. A large part of the annual supply continued to be provided by imports of nitrogenous, phosphatic and potassic varieties in 1963, but domestic output has increased and new plants were planned or under construction. Irish Nitrogen, Ltd., a semi-State body, continued work on a 150,000-ton nitrogenous fertilizer plant at Arklow (County Wicklow), near the now defunct Avoca copper mine. Original plans called for the use of Avoca pyrite but, under revised plans, domestic and imported sulfuric acid, petroleum byproducts, and fuel oil will be utilized at the plant.

Digitized by Google

Shell Chemical Co. joined with Albatross-Windmill Fertilizer Co. to form Shell and Albatross, Ltd. This new company, expected to produce chemicals as well as fertilizers, has its headquarters at New Ross (County Wexford), where Albatross-Windmill has a new 100,000-ton superphosphate factory. Superphosphate capacity of Shamrock Fertilizer Company, Ltd., at North Quay (County Wicklow) was recently enlarged to 100,000 tons per year.

Gypsum.—Production at the Kingscourt (County Cavan) deposit of Gypsum Industries, Ltd., continued at a rate of 100,000 tons per year. This company also controls deposits in Counties Meath and Monaghan. A large gypsum deposit reportedly was discovered at Glengevlin (County Cavan) during unsuccessful drilling for oil.

Sulfur.—Sulphac, Ltd., a company formed by W. and M. Goulding, Ltd., Ireland's leading fertilizer company, and Freeport Sulfur Co., New York, has sulfuric acid plants in Cork and Dublin. The latter is a new plant. Sulphac's sulfur supply is principally from the U.S. gulf coast. Pyrite from Spain had formerly been used in older and smaller plants.

MINERAL FUELS

Peat.—Output of sod (machine turf) peat remained higher than that of milled peat but has been gradually reduced in recent years; milled peat output has expanded rapidly. This trend toward emphasis on milled peat is due to increased demand for briquetting and fuel in the newer thermal powerplants. The main uses of sod peat have been in domestic and industrial heating and in older powerplants. Peat moss is largely baled and exported for agricultural use.

The government's current 5-year Economic Development Program (1959–64) called for extensive bog drainage work, which continued in 1963. Railroad and bridge construction to and in bog areas also has been part of the program. The Bord na Mona (Peat Development Board), responsible for providing an adequate peat supply for powerplants and home fuel uses, produced a large part of the milled peat, including that for conversion to briquets. The board also produced a significant share of the country's sod peat. During the year ending in March 1963, the board produced 1,543,000 tons of milled peat, the highest achieved by the company and a 14-percent increase in briquets over the preceding annual period; 24,000 tons of sod peat; and 301,000 bales of peat moss. A large part of the total sod peat output was produced by peat farmers.

Exports of peat moss during the year ending March 1963 increased considerably over those of 1962 and went to Great Britain, the Channel Islands, the Canary Islands, and the United States. The board operated briquet factories at Boora, Derrinlough, Croghan, and Lullymore, all in County Offaly. These plants were constructed during 1959–62 and have a total annual capacity of approximately 300,000 tons.

Petroleum.—Ambassador Ireland Oil Co., Ltd., a consortium of Ambassador Oil Co. of Texas, Conoco, and Sohio, continued its exploration program for oil into 1963, when the fourth hole was in progress. This Ireland-based company operated under contract with the government, which granted extendable 5-year exploration rights. Drilling

Digitized by Google

commenced in 1960, and during 1960–62 three dry holes totaling 23,000 feet were drilled. Drill site selection was based on aerial, seismic, and surface geologic investigations.

The Irish Refining Co., Ltd., of Whitegate (County Cork), Ireland's only petroleum refinery, which went into production in 1959, continued to expand output of gasoline and fuel oils to meet rising demand in the country. Forty percent of Irish Refining is owned by Esso, 40 percent by British Petroleum-Shell, and 20 percent by Caltex. Refinery capacity is 45,000 barrels per day.

During 1963 production from this refinery provided for nearly all the gasoline consumption of 3 million barrels, an exportable surplus of distillate fuel oil beyond consumption of 2.4 million barrels, and a large part of residual fuel oil requirements of 5.4 million barrels. Irish Refining discontinued production of jet fuel and kerosine, supplies of which were subsequently provided by imports from Great Britain. Lubricants, liquefied petroleum gas, and other minor petroleum products also are supplied principally by imports.

Irish Shell and British Petroleum, the largest wholesale suppliers of petroleum products in Ireland, opened an oil depot at Limerick in 1962. This depot, with storage capacity of 150,000 barrels, is supplied with products from Whitegate refinery and aviation fuel from Great Britain.

The Mineral Industry of Italy

By F. L. Klinger [1]

ITALY'S mineral industry is the third most important in the European Economic Community (EEC). Although the country is relatively deficient in most basic industrial raw materials such as the common metals and mineral fuels, it has become increasingly important to the world's mineral economy as a market for raw materials produced by other countries. Based principally on imported materials, the Italian iron and steel and petroleum industries have shown spectacular growth during the past 10 years. Italy now ranks sixth in free-world steel production and has the largest petroleum refining capacity in Western Europe.

Italy's gross national product in 1963 was estimated at Lit28,165 [2] billion, equivalent to US$45 billion. The gross industrial product (at current prices) was estimated at Lit10,948 billion (US$17.5 billion), of which 1.9 percent was attributed to the mining industry, 2.7 percent to the petroleum and coal derivatives industry, 3 percent to production of building materials, and 6 percent to the metallurgical industry. Although the total government revenue obtained from the mineral industry was not available, it may be of the order of 25 percent (the petroleum industry alone accounted for 14 percent of all government revenue in 1962 and 1963).

Employment in the mining industry in 1963 was estimated at 102,000 or about 2 percent of the industrial labor force. In addition, an estimated 500,000 or 9 percent of industrial labor was employed in primary metal extraction and processing, in manufacturing petroleum- and coal-derivatives, and in processing of construction materials. Employment in the mining industry declined about 2 percent as compared to 1962 but may have increased to some extent in the minerals processing industries because of new plants completed during the year.

High production costs and foreign competition continued to be the main problems of the industry in 1963. Labor costs increased as much as 25 percent as new contracts were negotiated during the winter of 1962–63 in the mining and processing industries. Efforts to reduce costs have led to increased production efficiency through installation of modern machinery and centralization of production; a prime example of this trend is the concentration of Italy's iron and steelmaking facilities in large integrated plants at coastal locations. The rising costs of production in 1963 also increased the pressure on government

to relax certain controls over prices and plant construction, notably in the petroleum industry.

TABLE 1.—Employment in Italian mineral-based industries in 1951 and 1961

Industry	Employment	
	1951	1961
Extractive:		
Metallic minerals	23,768	20,506
Nonmetallic minerals	70,567	72,690
Mineral fuels	24,327	10,661
Manufacturing:		
Metallurgical industry (primary)	145,071	191,689
Petroleum and coal derivatives	18,715	23,984
Nonmetallic mineral processing	206,668	311,546

Source: Istituto Centrale di Statistica (Rome), Annuario di Statistiche Industriali [1962]. V. 7, 1963, p. 117.

The lead, zinc, and sulfur industries continued to receive protection from foreign competition, under article 226 of the Rome Treaty, to allow reorganization and improvements in competitive position. In December the EEC agreed to extend the protective measures for an additional year in the cases of lead and zinc. Full protection for the sulfur industry was scheduled to expire in December but partial protection was to continue until 1968.

GOVERNMENT POLICIES AND PROGRAMS

The Italian Government participates to a large extent in the mineral industry. Most iron and manganese mining, iron and steel production, and a portion of the cement industry are controlled by the government through its organ, Istituto per la Ricostruzione Industriale (IRI). The government agency for metallic ores, Azienda Minerali Metallici Italiana (AMMI), accounts for about 20 percent of Italian lead and zinc production as well as other metals, and is responsible for coordinating exploration and development of the country's metallic mineral resources. A government-owned company, Ente Nazionale Idrocarburi (ENI), produces most of Italy's crude petroleum and natural gas, controls or has interests in about 25 percent of the nation's petroleum refineries, and conducts most of Italy's foreign operations in the petroleum field. The government also controls most of the country's electric-power industry as a result of nationalization in 1962.

The lead, zinc, and sulfur industries continued to be subsidized by the government in 1963. Financial aids were also maintained in other mining sectors such as the Sardinian coal-mining industry, and in mercury mining where the high production tax was finally abolished in 1962.

Generally, Italian trade policy encourages imports of minerals or metals which are needed for the manufacturing industry but restricts or imposes duty upon materials which can be produced in adequate amounts within the country. In metals, for example, imports of ores of aluminum, copper, iron, and manganese are duty-free but ingots or semimanufactures are usually taxed at basic rates ranging from 5 to 18 percent ad valorem. Additional tariff protection is given to lead,

Digitized by Google

zinc, and sulfur but the Italian tariffs are scheduled to be replaced by lower EEC rates in 2 or 3 years as the "transition" periods end.

SOURCE MATERIAL

The principal sources of information were statistical publications of the Italian Government or of its affiliated organizations operating within the mineral industry. Statistics on production and foreign trade were mainly obtained from publications of Istituto Centrale di Statistica (ISTAT), especially "Annuario di Statistiche Indusriali" and "Statistica Mensile del Commercio con l'Estero." For the iron and steel industry, the principal sources were "Rilevazioni Statistiche" (published in Milan by Associazione Industrie Siderurgiche Italiane (ASSIDER)), and "Siderurgia" (published in Luxembourg by Istituto Statistico delle Comunità Europee); for the nonferrous metals, "Metalli Non Ferrosi e Ferroleghe" (published by AMMI) and for the petroleum industry, various publications by the Ministry of Industry and Commerce including "Bollettino Petrolifero," "Bollettino Ufficiale degli Idrocarburi," and "Industria del Petrolio in Italia". Information on oil and gas exploration and development in Italy was largely drawn from the annual summaries published in the "Bulletin of the American Association of Petroleum Geologists." Much additional information of both specific and general nature in all fields was obtained from dispatches and statistical summaries compiled by the U.S. Embassy in Rome, from various industrial periodicals, and from company reports.

In general, Italian publications were preferred over foreign sources and where detailed studies involving translations were impracticable, an effort was made to check foreign information with official sources. Also, where ISTAT foreign trade statistics differed from those published by government agencies more directly concerned with the mineral industry, as in the case of coal and petroleum, the industrial sources were considered more authoritative.

PRODUCTION

The overall volume of production in the mining industry in 1963 declined by 4.5 percent as compared with 1962. Output of solid fuels decreased 20 percent, metallic minerals 15 percent, nonmetallic minerals 5 percent, and crude petroleum production decreased about 1 percent. Despite the general decrease, increases were shown in production of several mineral commodities such as bentonite, potash salts, salt, natural gas, feldspar, and bituminous rock. In the manufacturing industry, production of aluminum as well as iron and steel increased whereas output of lead and zinc dropped slightly below the levels of 1962. Cement production increased by 10 percent, and output of petroleum products rose nearly 15 percent.

Primary (cement)	6,988	4,600	4,700	4,268	(1)
Secondary (refined)	19,000	15,500	14,000	12,000	(1)
Semimanufactures, including alloys	195,300	233,900	275,000	294,000	323,000
Alloys, in ingots, from scrap	16,300	27,700	33,000	31,500	(1)
Gold:					
Ore (0.007 to 0.01 percent Au)	1,358	1,411	246	----------	----------
Metal, troy ounces	3,261	3,310	600	(1)	(1)
Iron:					
Ore (47 to 49 percent Fe), thousand tons	1,237	1,245	1,203	1,151	1,006
Pyrite cinders [2], do	(1)	(1)	(1)	924	888
Pig iron, do	2,098	2,683	3,056	3,556	3,741
Ferroalloys, do	94	141	145	122	127
Steel (ingot tons), do	6,762	8,229	9,124	9,757	10,157
Hot rolled, do	5,202	6,631	7,198	7,547	7,980
Cold rolled, do	913	1,166	1,157	1,306	1,664
Lead:					
Ore (62.5 percent Pb)	83,225	79,203	76,002	66,307	51,117
Metal:					
Primary	44,042	41,651	45,150	41,986	41,934
Secondary, from scrap and residues	(1)	(1)	6,100	4,800	(1)
Alloys, in ingots	6,000	10,000	14,000	12,000	(1)
Semimanufactures	(1)	36,072	38,000	38,000	(1)
Magnesium	4,500	5,446	5,595	5,703	5,508
Manganese ore (25 percent Mn)	50,374	46,804	47,218	44,500	45,287
Mercury:					
Ore	247,203	294,259	291,110	275,119	256,941
Metal, 76-pound flasks	45,833	55,492	55,405	54,535	54,506
Pyrite (including cupriferous pyrite)	1,517,800	1,546,460	1,580,186	1,584,524	1,398,840
Silver (999/1,000 fine), troy ounces	1,060,749	943,946	973,139	929,832	[3] 1,005,941
Tungsten ore (65 percent WO_3)	5	7	2	1	2
Uranium ore	687	964	60	(1)	(1)
Zinc:					
Ore (52.6 percent Zn)	224,617	232,171	239,836	236,361	205,557
Ore (19 to 24 percent Zn)	47,655	45,093	33,772	31,736	7,252
Metal:					
Primary	73,951	79,869	78,403	77,671	73,596
Refined from scrap and residues	5,400	5,900	5,200	4,400	(1)
Semimanufactures	(1)	8,540	8,700	9,800	(1)
Nonmetals:					
Asbestos	47,662	[3] 51,423	56,984	55,553	57,532
Barite (crude)	121,322	143,267	141,520	121,915	106,599
Bentonite	95,910	126,534	131,333	111,357	142,927
Borax	9,720	11,435	13,402	(1)	(1)
Boric acid (96 to 97 percent in acid)	2,489	2,657	1,772	1,378	514
Bromine:					
Elemental	714	1,278	1,512	(1)	(1)
Inorganic bromides	170	200	282	(1)	(1)
Organic bromides	338	354	536	(1)	(1)
Celestite (90 percent)	(1)	830	1,070	600	654
Cement, thousand tons	14,227	15,849	17,991	20,248	22,087
Cement rock, do	(1)	(1)	(1)	3,985	4,426
Clays:					
For bricks and terracotta, do	18,241	18,752	22,448	(1)	(1)
For cement (including clay shale), do	2,257	2,338	2,201	(1)	(1)
Bleaching and refractory	102,518	99,186	179,673	179,965	353,556
"Bianchetto" (kaolinitic and bauxitic)	11,500	----------	12,000	(1)	(1)
Kaolin	[3] 58,037	86,815	[3] 86,154	73,822	73,562

TABLE 2.—Production of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Nonmetals—Continued					
Construction materials:					
Asphalt rock (for surfacing)..thousand tons	406	407	106	105	115
Bituminous rock.....do			149	152	183
Building and ornamental stone: [4]					
Marble in blocks.....do	671	835	992	889	867
Other stone, in blocks, slab, etc...do	8,898	12,432	13,196	(1)	(1)
Broken stone in quarries.....do	4,382	7,225	5,783	(1)	(1)
Sand and gravel.....do	20,329	25,632	28,768	34,700	(1)
Miscellaneous.....do	170	165	184	(1)	(1)
Diatomite	51,799	47,072	57,198	(1)	56,589
Dolomite	434,338	489,744	650,862	(1)	(1)
Earths:					
Coloring	8,109	9,104	6,608	(1)	(1)
Foundry	284,390	342,816	350,127	(1)	(1)
Feldspar	60,952	86,441	94,699	92,588	101,819
Fertilizers:					
Superphosphate (P_2O_5 content)	264,899	228,913	246,253	221,861	242,960
Nitrogenous (N_2 content)	521,273	648,871	669,686	643,608	682,506
Potassic (K_2O content)	(1)	(1)	137,200	177,900	187,500
Fertilizer materials:					
Potash salts (15 percent K_2O)	76,415	331,508	908,320	1,037,995	1,263,676
Thomas slag	91,000	100,000	132,000	121,000	118,000
Leucite (10 percent K_2O)	(1)	(1)	895	80	(1)
Fluorspar	157,933	162,347	156,564	155,559	124,495
Graphite	3,136	3,718	4,068	3,359	1,709
Gypsum [5].....thousand tons	1,910	1,825	2,001	[6] 2,972	(1)
Iodine (crude).....kilograms	15,028	12,570	12,547	11,000	(1)
Lime (hydraulic).....thousand tons	(1)	(1)	5,200	5,355	(1)
Limestone:					
For building purposes.....do	8,514	10,521	8,573		
For lime and cement.....do	17,816	19,943	19,471	52,300	(1)
Other.....do	11,463	15,382	13,407		
Magnesite	6,860	5,973	6,784	8,414	6,815
Pozzolan.....thousand tons	2,772	3,170	2,915	3,012	(1)
Pumice.....do	234	313	257	317	(1)
Pumicite	133	113	146	(1)	(1)
Salt:					
Rock salt.....thousand tons	1,282	1,582	[3] 1,626	1,727	1,943
Evaporated.....do	708	1,019	1,216	[6] 1,200	(1)
Silica sand.....do	1,648	1,903	2,097	2,404	(1)
Sulfur:					
Ore (25 to 30 percent S)	1,431,450	1,278,330	1,221,155	1,083,859	965,858
Concentrate (90 percent S)	33,572	56,786	75,787	90,042	94,911
Fused, in briquets	121,511	81,020	69,750	53,919	41,788
Talc and steatite	109,258	124,391	[3] 143,626	127,161	135,520
Mineral fuels:					
Asphalt rock, for distillation	(1)	(1)	81,159	48,988	98,907
Coal:					
Anthracite	31,236	19,537	23,654	16,160	13,797
Sulcis coal	707,424	717,141	717,574	676,024	571,425
Briquets	24,000	27,000	29,000	59,000	127,000
Coal derivatives	234,730	264,054	285,864	301,962	306,552
Coke:					
From coke ovens.....thousand tons	3,054	3,715	3,876	4,326	4,460
From gas ovens.....do	(1)	(1)	(1)	756	719
Lignite:					
Picean (high grade).....do	48	7	4	1	
Xiloid (20 percent H_2O).....do	1,174	1,239	1,521	1,775	1,366
Natural gas.....thousand cubic meters	6,117,549	6,447,224	6,862,710	7,150,580	7,267,598
Natural gasoline.....thousand 42-gallon barrels	560	551	535	515	515
Petroleum:					
Crude.....do	11,551	13,613	13,434	12,308	12,155
Refined products.....do	191,929	226,032	269,253	321,563	372,579

[1] Data not available.
[2] Estimate (total of material consumed in agglomerating plants plus net exports).
[3] Revised figure; supersedes that given in commodity chapter, volume 1.
[4] Not including limestone.
[5] Not including alabaster or dimension stone.
[6] Estimate.

TRADE

Mineral and metal exports in 1963 were valued at US$587 million, or 11.6 percent of the value of all exports. Mineral fuels (principally

Digitized by Google

refined products) were valued at US$281 million, or 5.5 percent of all exports, followed by metals (US$211 million, or 4 percent) and nonmetals (US$95 million, or 2 percent).

Imports of minerals and metals were valued at US$2.1 billion or 28 percent of the value of all imports. Metals were valued at slightly more than US$1 billion, or 14 percent of all imports, followed by mineral fuels (US$943 million, or 12.5 percent) and nonmetals (US$124 million or 1.6 percent). Iron and steel materials were the most important category, valued at US$682 million, followed by crude petroleum (US$665 million), coal and coke (US$176 million), copper (US$160 million), and other minerals (US$177 million).

TABLE 3.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963
Metals:				
Aluminum:				
Ore	--------	--------	930	(1).
Ingots and scrap	91	135	252	Switzerland 137.
Semimanufactures	6,797	7,267	8,284	United States 3,970; West Germany 251; Greece 199.
Antimony	1	3	--------	
Beryllium:				
Ore	37	--------	--------	
Oxide—kilograms	240	--------	3,000	(1).
Bismuth	1	3	--------	
Cadmium	42	83	3	(1962: Belgium-Luxembourg 19; Republic of the Congo (Léopoldville) 15.)
Chromium:				
Chromite	--------	--------	1,500	France 1,500.
Semimanufactures	2	--------	--------	
Cobalt	1	4	--------	
Copper:				
Ore [2]	3,021	4,314	2,534	Spain 1,980; Switzerland 342.
Raw, including metalline	37	36	--------	
Ingots and scrap	287	363	269	Belgium-Luxembourg 131; West Germany 111.
Alloys	7	2	1	(1).
Semimanufactures	12,755	9,681	8,990	Israel 1,767; Portugal 776; Switzerland 664; Iran 639.
Iron and steel:				
Pyrite cinder [3]—thousand tons	720	617	661	Austria 352; Netherlands 115; Belgium-Luxembourg 81.
Scrap—do	1	2	2	France 1; Belgium-Luxembourg 1.
Pig iron, sponge and grit—do	1	1	1	(1).
Ferroalloys—do	19	8	6	Australia 1; Austria 1; West Germany 1.
Steel:				
Ingots, blooms and billets—do	133	111	88	Spain 52; Switzerland 34; Argentina 2.
Other rolled—do	757	839	792	(See table 9.)
Lead:				
Ore [2]	4,903	5,603	4,460	Austria 4,000.
Ingots and scrap	28	90	113	(1).
Semimanufactures	187	86	406	Morocco 305.
Magnesium:				
Crude and scrap	4,439	4,559	4,161	West Germany 2,977 (crude).
Wrought	330	372	332	Norway 119; West Germany 80; Austria 69.
Manganese ore	556	644	738	West Germany 738.
Mercury—76-pound flasks	32,680	35,726	75,728	Japan 13,222; United Kingdom 13,068; West Germany 12,204; France 8,639; United States 7,803; Belgium-Luxembourg 2,741.
Molybdenum	13	1	--------	
Nickel:				
Scrap	5	--------	2	(1).
Semimanufactures [4]	734	728	987	Iran 410; Morocco 247; Turkey 44.

See footnotes at end of table.

TABLE 3.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963
Metals—Continued				
Precious metals: [4]				
Gold...thousand troy ounces	132	6	(1)	(1).
Platinum and related do... metals.	16	14	26	United Kingdom 18; United States 2, West Germany 1.
Silver...do...	158	80	103	(1).
Tantalum [5]			6	(1).
Tin:				
Ingots and scrap...long tons	11	23	6	(1).
Alloys...do...	17	190	16	(1962: Sweden 141.)
Semimanufactures...do...	19	53	8	(1).
Tungsten:				
Ore		11		
Powder and other		8	2	(1).
Uranium and thorium...kilograms	100			
Zinc:				
Ore [3]	78,091	67,006	41,309	France 11,585; Belgium-Luxembourg 11,490; Austria 10,060.
Slab	6,366	2,122	302	United States 268.
Alloys and scrap	6	2	1	(1).
Semimanufactures	365	382	309	Switzerland 227.
Zirconium ore		2	38	(1).
Other metallic ores [3]	253	5,693	6,487	United Kingdom 4,822; Belgium-Luxembourg 1,352.
Other metals...kilograms	2,400	700		(1962: Switzerland 200; United Kingdom 100; U.S.S.R. 100.)
Nonmetals:				
Abrasives (natural):				
Corundum and garnet	517	11	6	(1).
Emery	63	12	61	(1).
Pumice stone	100,446	135,445	343,825	West Germany 177,931; United States 97,776.
Other	89	117	495	(1).
Andalusite, kyanite, etc	54	303	218	(1).
Asbestos	9,206	7,890	6,412	France 2,659; Belgium-Luxembourg 743.
Barite and witherite	38,642	46,773	22,408	Nigeria 4,550; Rumania 3,300.
Bentonite	19,358	28,234	30,061	Libya 12,497. (1962: Switzerland 11,005.)
Chalk	389	760	225	(1).
Clay and earth:				
Coloring earths	831	1,118	(1)	(1).
Diatomite	4,543	2,949	1,332	(1961 and 1962: West Germany.)
Fuller's earth	59	97	23	(1).
Kaolin	94	111	272	(1).
Kaolinitic earth	18	3	48	(1).
Refractory clays	595	969	869	(1).
Other clays	195	103	282	(1).
Construction materials:				
Building and ornamental stone:				
Alabaster	669	859	884	(1).
Marble	217,357	238,468	251,951	West Germany 58,490; United States 37,988: France 23,485; United Kingdom 19,730; Lebanon 13,431.
Serpentine	(1)	874	987	Switzerland 357; West Germany 294.
Other	28,986	32,580	32,024	Switzerland 8,956.
Crushed stone, chips and powder.	283,316	300,955	339,859	West Germany 49,321; Belgium-Luxembourg 43,407; Switzerland 36,925.
Cement, including clinker	71,567	135,142	149,176	Sudan 51,806; Switzerland 22,242; Libya 14,722.
Gypsum and anhydrite	7,953	7,185	9,367	France 1,014.
Lime	9,488	13,555	18,646	Libya 14,600.
Limestone	1,115	1,054	702	(1).
Cryolite		5	1	(1).
Dolomite	10,167	11,345	11,526	Switzerland 5,151; Egypt 2,275.
Feldspar	16,654	17,005	19,433	West Germany 11,700; Netherlands 2,500.
Fertilizers:				
Nitrogenous...thousand tons	1,396	1,344	1,462	Mainland China 412; Egypt 241; Spain 179; Greece 164; Yugoslavia 142.
Phosphatic...do...	98	115	120	Greece 29; Yugoslavia 21; Nigeria 6.
Potassic...do...	59	65	77	Japan 26; United States 19; Indonesia 10.
Fluorspar	67,069	49,116	38,268	United States 34,755.
Graphite	1,695	1,613	1,516	France 1,091.
Lithium minerals	(1)		20	(1).
Magnesite, raw and calcined	180	203	108	(1).
Mica [6]	61	40	48	(1).

See footnotes at end of table.

TABLE 3.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal destinations, 1963
Nonmetals—Continued				
Precious and semiprecious stones (natural):				
Diamonds:				
Uncut thousand carats or semifinished.	(1)	10	(1 7)	Value (thousand lire): United Kingdom 116,357.
Industrial do	(1)	35	7 35	(1).
Other do	(1)	10	(1 7)	(1).
Other stones kilograms	1,192	571	1,087	(1).
Pyrite	227,584	158,268	101,853	Netherlands 53,055; Switzerland 37,238.
Quartz:				
Crushed or powdered	257	586	191	(1).
Other	9,394	3,967	5,038	(1).
Salt	43,080	28,820	75,458	Norway 31,721; United Kingdom 21,041.
Sands:				
Feldspathic and kaolinitic	91	270	1,068	(1).
Siliceous	626	3,616	1,686	(1).
Other	119,125	189,250	175,868	Switzerland 174,025.
Strontium minerals	289	91	89	(1).
Sulfur:				
Ore	-------	991	-------	
Crude and refined	41,120	14,071	7,657	Yugoslavia 4,273; Cyprus 1,290; Thailand 577.
Talc and steatite	50,173	51,602	47,173	United States 15,700; United Kingdom 6,541; West Germany 5,311.
Other mineral materials	22,309	34,895	46,331	United Kingdom 45,995.
Other ashes and residues, including kelp ash.	24	85	17	(1).
Mineral fuels:				
Asphalt and bitumen (natural)	701	251	398	(1).
Asphaltic and bituminous rock	8,482	8,229	8,753	(1961: United Kingdom 8,436.)
Coal	5,567	4,708	24,143	France 21,784.
Coal tar and other derivatives	2,616	5,260	3,914	France 3,139.
Coke and semicoke	166,439	173,531	149,068	Austria 64,543; Switzerland 26,078; Yugoslavia 20,693.
Lignite	20	-------	-------	
Peat	-------	6	-------	
Pech	20,913	30,016	44,292	France 22,870; Spain 18,370.
Petroleum:				
Crude thousand 42-gallon barrels.	3,248	2,275	1,222	United Kingdom 1,140.
Refined products:				
Gasoline do	15,272	16,063	15,555	Switzerland 3,287; Austria 3,175; France 1,404; United Kingdom 1,220; Sweden 777.
Kerosine do	2,977	2,802	3,636	Netherlands 590; Switzerland 516; United Kingdom 456.
Distillate fuel oil do	19,010	25,335	30,876	Switzerland 9,570; Netherlands 4,821; France 3,869; West Germany 3,180.
Residual fuel oil do	17,109	16,772	17,434	United Kingdom 3,549; Switzerland 2,201; Austria 1,985; Algeria 1,542; Cyprus 1,251.
Lubricating oils do	117	193	283	Switzerland 99; Austria 40.
Liquefied petroleum gas do	161	193	545	France 123; Brazil 96; Lebanon 74; Libya 30.
Asphalt do	720	746	863	Austria 428; Switzerland 187.
Other do	119	66	90	Switzerland 68.

Asphalt—do	1	2	1	(1).
Total petroleum products—do	(1)	22,959	25,549	

[1] Data not available.
[2] Includes ash, slag, dust, and other waste of iron and steel.
[3] Includes 152,000 tons of used rails.
[4] Includes 66,000 tons of used rails.
[5] Includes alloys.
[6] Mostly semiprecious.
[7] Includes 20,000 kilograms of chalcedony powder.

COMMODITY REVIEW

METALS

Aluminum.—Italian production of primary aluminum in 1963 increased by 12 percent as compared with 1962. The increase was almost entirely due to a 10,000-ton rise in production by plants of the Montecatini Co., particularly a new plant at Bolzano which entered production during the year. Montecatini accounted for two-thirds of the national production in 1963; 29 percent was produced by Società Alluminio Veneto per Azioni (SAVA) at Porto Marghera and 5 percent by a subsidiary of the Aluminium Company of Canada at Turin.

Imports of primary metal in 1963 increased by 23 percent over those of the previous year, and imports of scrap and semimanufactures rose by 11 and 57 percent, respectively. Italy's consumption of primary aluminum appeared to exceed 145,000 tons, but not all of the Italian production was absorbed by the domestic market because of competing imports from the United States, Canada, Norway, and Austria.

Digitized by Google

Bauxite production fell 13 percent because of decreasing reserves at Montecatini's San Giovanni Rotondo mine near Foggia. This mine produced 72 percent of Italian bauxite in 1963 as compared with 77 percent in 1962. The decreasing reserves caused Montecatini to begin intensive geological exploration in areas known to contain bauxite in the Matese Mountains of Campania.

The drop in domestic bauxite production was compensated by a 23 percent increase in imports. Imports from Yugoslavia increased 43,000 tons, 23 percent over those of 1962, and imports from new sources (Australia and Surinam) made up for a 27,000-ton reduction in imports from India.

New plant facilities added during the year by Montecatini included rolling mills and extrusion presses at Belluno and Porto Marghera, and a new plant was under construction at Porto Marghera. Most facilities were intended to increase production of aluminum sheeting and very wide plates. The company's plan to set up an aluminum reduction plant with a capacity of 100,000 tons of metal per year in Sardinia was temporarily suspended.

Copper.—Italian copper resources are small and are of low grade. Domestic ores consist of two types:

Chalcopyrite concentrates (containing about 20 percent copper) produced as byproducts from lead, zinc, and other metal mines in Sardinia and northern Italy, and cupriferous pyrite containing about 2 percent copper. Concentrate production has averaged less than 3,000 tons annually since 1958 but apparently increased in 1963 despite the closing of the Agordo mine near Belluno during the previous year. Production of cupriferous pyrite averaged about 80,000 tons per year from 1960 through 1962 and may have continued at this level during 1963. Most of the copper produced from these ores was probably used in manufacturing copper sulfate, of which Italy has produced about 75,000 tons annually since 1948.

Total copper consumption in 1962 was 308,000 tons including 214,000 tons of refined copper. Of total consumption, 83 percent was used for copper and alloy semimanufactures, 11 percent for copper and alloy castings, and 6 percent for chemicals. Incomplete data indicate that total consumption increased in 1963, as consumption of refined copper rose by 6 percent and production of semimanufactures increased by nearly 10 percent.

Production of primary copper in 1963 was about 1 percent of total consumption. Output of refined copper was estimated at 12,000 long tons [3] and an estimated 30,000 tons of copper-alloy ingots were produced from scrap. Production of semimanufactures increased by 29,000 tons, principally in copper wire (11,800 tons) and in alloy rods and sections (13,700 tons). Employment in the semimanufactures industry increased to an estimated 19,000 in 1963.

Exports of copper concentrates in 1963 amounted to about half of production. Other copper exports (in percent of national production) were: copper sulfate (6 percent), semimanufactures (3 percent), and refined copper (2 percent). These exports were valued at US$9.7 million.

[3] The British Bureau of Non-Ferrous Metal Statistics (Birmingham.) Bulletin for June 1964. V. 17, No. 6, Aug. 18, 1964, p. 8.

Digitized by Google

Imports of copper in 1963 totaled about 257,000 tons, 5 percent less than in 1962. Refined copper made up 83 percent of the tonnage, followed by scrap (8 percent), semimanufactures (4 percent) and raw copper (3 percent). In both quantity and value, copper was the principal metal imported (after iron and steel). Imports were valued at US$160 million.

Iron and Steel.—The Italian iron and steel industry is the third largest of the European Coal and Steel Community (ECSC) and the fourth largest in Western Europe. In 1963, Italy produced 14 percent of ECSC steel and 2.7 percent of world output. The industry has ranked eighth in world production since 1958.

In the Italian economy, the iron and steel industry in 1963 accounted for an estimated 2 percent of the gross national product and 5 percent of gross industrial output. The industry has tripled productive capacity over the past 10 years and continued its growth in 1963 as steelmaking capacity increased by 8 percent and a major new steelworks was nearing completion at Taranto. Potential for growth of the industry was illustrated by steel consumption which rose 12 percent over that of 1962 and exceeded productive capacity by more than 20 percent. Although steel production and sales continued to be hampered by foreign competition, investments in production equipment and services for the industry were estimated at US$335 million, more than twice the figure for 1962. Employment remained at approximately the same level as in 1962, with the 1963 monthly average being slightly higher and the yearend total slightly lower than in the previous year. Relative stability in labor relations was achieved by early 1963 as 3-year contracts were signed in both public and private segments of the industry. The contracts provided for a 12-percent raise in minimum wage, a reduction in the workweek (to 43 hours), and other benefits. At the end of 1963, the industry employed 58,500 persons, or 0.7 percent of all industrial labor.

The industry is heavily dependent on imported raw materials. All of the coking coal, most of the iron ore and alloying materials, and half of the scrap requirements were imported in 1963. The reliance on imports and the need to reduce costs have resulted in concentration of Italy's primary iron and steel production in large integrated steelworks on the coast at Genoa, Piombino, Naples, and Taranto. Most of the ferroalloys and special steels are produced in the northern interior where there is abundant hydroelectric power.

The largest organization in the iron and steel industry is Società Finanziaria Siderurgica (FINSIDER), a holding company which includes the steel firms of Italsider, Dalmine, and Terni as well as the mining organization, Società Mineraria Siderurgica (FERROMIN). The FINSIDER group, which is owned 50.55 percent by IRI, produced 91 percent of the pig iron and 53 percent of the steel produced in Italy in 1963. The remainder was produced by private firms, of which the largest are Fiat and A. F. L. Falck. Italsider, a combine of the Ilva, Cornigliano (SIAC), and Breda companies is the largest Italian producer as well as the largest single steel complex in Europe.

The main difficulties experienced by the industry during 1963 were cutbacks in steel production and a buildup of manufacturer's inventories which resulted from excessive imports of low-cost steel from

Digitized by Google

other member countries of the ECSC. This was due to the offering of steel at "dumping" prices by East European nations and the subsequent lowering of prices within the Community to levels which Italian producers were unable to meet. Decisions by the ECSC High Authority to forbid the "alignment" of ECSC prices to low East European quotations and to raise Community tariffs to the Italian level were expected to provide some relief during 1964. In the meantime the competitive position of the industry is expected to improve as productive capacity more closely approaches national demand and improvements in steelmaking efficiency continue. The oxygen process, already in use at the Cornigliano (Genoa) steelworks, was being installed at the Bagnoli (Naples) works in 1963 and will be the only process used at the Taranto works which was scheduled for completion in late 1964. The Taranto plant was expected to increase Italy's steelmaking capacity by an estimated 20 percent.

Iron Ore.—Italy has no significant deposits of high-grade iron ore. Iron concentrate produced in 1963 accounted for 19 percent of iron raw material consumption and an estimated 16 percent of iron production. Conventional ores provided 13 percent of the total iron requirements, and pyrite cinders provided 3 percent. The tonnage of pyrite cinders consumed was only about one-fourth of total production, as most of this product is normally exported to other West European countries.

In 1963 iron ore production and mine employment decreased by 14 and 17 percent, respectively, continuing declines which began in 1961. The decreased activity was apparently due to the relatively high costs of production and increased imports of higher grade ore. The average iron content of domestic crude ore is usually below 40 percent and practically all of the ore must be beneficiated before use. Of the total crude ore produced in 1963, 56 percent of the tonnage and 80 percent of the iron was recovered as concentrate. Concentration methods included screening, washing, spiraling, heavy-media and magnetic separations, flotation, and sintering. The main sources of production continued to be Elba (pyritic hematite-magnetite ores), Aosta (magnetite), the Bergamo-Brescia region (siderite), and Sardinia (oxide-carbonate-silicate and magnetite ores).

Production of pyrite cinder appeared to be slightly less than in 1962, although information on plant stocks was not available. Consumption in iron ore agglomerating plants decreased by 25 percent, probably because of competition from imported iron ore. The competitive position of Italian pyrite cinder is expected to improve, however, when Montecatini's new roasting plant at Follonica (southeast of Piombino) is completed. This plant, which was nearing completion at the end of 1963, will produce about 1,100 tons per day of pelletized iron concentrate containing 65 to 66 percent iron. Production was scheduled to begin early in 1964. The magnetizing reduction process, which employs fluidized-bed techniques, was developed by Montecatini and Dorr-Oliver, Inc.

Imports of iron ore increased by nearly 1 million tons and were 22 percent greater than in 1962. South American countries supplied 43 percent of all imports, followed by Africa (30 percent), India (11 percent), and Sweden (9 percent). Imports from Peru and Chile

Digitized by Google

were doubled, and deliveries from Algeria, Brazil, and Sweden were substantially increased as imports from India fell by 450,000 tons, or nearly 50 percent below the level of 1962.

Scrap.—Estimated total scrap consumption in 1963 was 7.4 million tons, an increase of about 5 percent or 400,000 tons as compared with 1962. As in 1962, about half of scrap requirements were met by imports, with the principal supplying countries being West Germany, the United States, and France, in that order. About 60 percent of imported scrap came from EEC countries.

Pig Iron.—Production of pig iron in 1963 increased by 185,000 tons, 5 percent over that of the previous year. The increase was mainly due to the first full year's operation of a new blast furnace at the Cornigliano steelworks near Genoa. The new furnace, which has an annual capacity of 800,000 tons of pig iron, began operation in the summer of 1962 and increased the industry's productive capacity to 4,140,000 tons.

Production in 1963 was 90 percent of total capacity and constituted 7 percent of the EEC output. Hematitic (Martin) iron made up 76 percent of the total production; phosphorous (Thomas) iron made up 18 percent; and 6 percent was produced in electric furnaces. Domestically produced pig iron accounted for 37 percent of Italy's crude steel output, as compared with 72 to 92 percent in other EEC countries.

Imports of pig iron were 12 percent more than in 1962. West Germany continued to be the principal supplier, followed by the U.S.S.R. As in 1962, about half of all imports were from EEC countries and 30 percent came from East Europe.

Ferroalloys.—Ferroalloy production in 1963 was 4 percent greater than in 1962 but was still about 12 percent less than the record productions of 1960–61. The principal gain was shown by ferrosilico-manganese which rose by 9,000 tons, or 35 percent, and small increases were

Digitized by Google

shown in most other items. Production of ferrochrome dropped by 50 percent, continuing a sharp decline which began in 1961, but apparent consumption (production plus net imports) was little changed from 1961–62 levels. Apparent consumption of total ferroalloys in 1963 increased by nearly 20 percent over the previous 2 years but much of this increase may have remained in plant stocks. Reported consumption of spiegeleisen and carbon-ferromanganese in steel production accounted for only 60 percent of the available supplies.

Net imports of ferroalloys in 1963 were nearly 40 percent above the previous year, with the principal increases shown by manganese ferroalloys and ferrochromium. France remained the principal supplier, although its share was reduced as imports from Belgium-Luxembourg increased by more than 10,000 tons and substantial gains were also made by West Germany, Norway, and Switzerland.

Exports of ferroalloys during the same period were about 27 percent less than in 1962. Shipments of ferromanganese nearly doubled but substantial decreases were apparent in ferrochromium and ferrosilicon with the latter more than 50 percent lower than in 1962. Exports to non-EEC countries increased during 1963.

Steel.—Italy's crude steel production in 1963 exceeded 10 million tons and was nearly 14 percent of EEC output. As compared to 1962, production increased by 4 percent, and productive capacity increased by 5 percent to approximately 11.1 million tons annually. Production was 91.5 percent of total capacity, slightly higher than in 1962, but the increase of 400,000 tons in production was small compared to domestic demand which rose by 1.5 million tons. Total steel consumption was estimated at 13.7 million tons and exceeded production by nearly 25 percent as compared with 20 percent in 1962. The rise in demand was

mainly due to increases of 25 percent in the automobile industry, 13 percent in the mechanical industry, and 4 percent in the construction industry.

Open-hearth steel made up about half of the total production, with 42 percent made in electric furnaces and 6 percent in Thomas converters. Special steel accounted for 12 percent of total production and included 564,000 tons of high-quality carbon steel as well as 657,000 tons of alloy steel. The alloy steel figure includes 506,000 tons of structural steel, 82,000 tons of stainless steel, and 46,000 tons of bearing steel.

Production of hot-rolled items in 1963 increased by 430,000 tons, 6 percent over that of 1962. The principal gains were shown in commercial bars and rods (up 235,000 tons) and coils (up 100,000 tons); these items constituted 36 percent and 20 percent, respectively, of total production. Hot-rolled sheet and strip made up 16 percent of production, followed by seamless tube (10 percent) and rails and heavy sections (10 percent). Production increases of 28 percent and 35 percent, respectively, were shown in cold-rolled sheet (up 360,000 tons) and tinplate (up 55,000 tons) as compared with 1962.

Exports of steel in 1963 were about 8 percent less than in 1962. The total tonnage decreased by 70,000 tons, principally in small-diameter bars, and in ingots, blooms, and billets. As in 1962, rolled steel products made up 85 percent of all exports, with the principal items being tubes (37 percent); uncoated sheet (25 percent); ingots, blooms, and billets (10 percent); and small-diameter bars (6 percent). Of all steel exports, 11 percent went to EEC countries as compared to 7 percent in 1962. Exports of steel to the U.S.S.R. and other East European countries probably fell at least 30 percent below the 1962 level; shipments of EEC treaty items [4] were one-third less and although data on tube products was incomplete, Argentina appeared to have replaced the U.S.S.R. as the principal importing country. Spain replaced Argentina as the principal destination of ingots and other crude forms.

Imports of steel increased by nearly 900,000 tons, 28 percent more than in 1962. Most of the increase occurred in flat rolled products such as coils (up 352,000 tons), sheet and strip (up 228,000 tons), and coated sheet (up 80,000 tons including a 50,000-ton increase in tinplate). Imports of steel ingots, blooms, and billets increased by 155,000 tons.

Rolled products constituted 82 percent of all steel imports, and ingots and other crude forms, 15 percent. Of EEC treaty items, Common Market countries supplied 60 percent followed by the U.S.S.R. and other East European countries (12 percent); Japan (9 percent); and other West European countries (9 percent). Imports from Japan increased to 351,000 tons as compared with 68,000 tons in 1962. Most of the Japanese steel was in coils for re-rolling.

General Steel Industry Expansion.—The iron and steel industry is engaged in an expansion program intended to increase steelmaking capacity to 15.8 million tons annually by 1966. Oxygen-steelmaking

facilities will make up 30 percent of this capacity. In 1964, total steelmaking capacity is expected to increase to more than 13 million tons when the new works at Taranto begins production late in the year. Initial capacity at Taranto will be about 2 million tons each for pig iron, ingot steel, and rolled products consisting chiefly of wide strip, sheets, and plates. A large-diameter pipe mill has been in operation since late 1961, using plates obtained from SIAC in Genoa until local production begins.

In oxygen steelmaking, two oxygen plants had been installed at the Cornigliano steelworks by October 1963 and were supplying six open-hearth furnaces. At Bagnoli, one oxygen plant was completed and two more were under construction. Facilities at Taranto will consist of two 285 to 330-ton basic oxygen converters, possibly the largest in the world.

Four blast furnaces were under construction in 1963; two at Taranto; one at Piombino; and one at Trieste. Italian pig iron capacity is expected to reach 5.9 million tons by the end of 1964 and 8.4 million tons by 1966. Italsider's cold-rolling plant at Novi Ligure (near Genoa) began production of cold-rolled sheet early in 1963. Initial capacity of the plant was 250,000 tons annually, to be increased to 850,000 tons by the end of 1964. The plant will be fed with hot-rolled flats from the Cornigliano and Taranto works.

A plant to produce rolled stainless steel products was under construction in 1963 at Terni in central Italy. The plant will have an initial capacity of 30,000 tons and is a joint venture of Terninoss S.p.A. and the United States Steel Corp.

Lead and Zinc.—Lead-zinc ores are one of the principal mineral resources of Italy. Mine production of zinc was the largest in Western Europe until 1963 when, because of cutbacks in Italian production, Spain became the principal producer and Italy's output was matched by West Germany. In mine production of lead, Italy ranks second

Digitized by Google

in the EEC (after West Germany) and fifth in Western Europe. Most of the cadmium and silver produced by Italy are obtained as by-products from the lead-zinc ores and are sometimes the deciding economic factors in mine operation. In addition, concentrates of fluorspar and barite are obtained from the mill operations.

Most of the mines are in Sardinia, principally in the Iglesias region. Other important deposits are worked in northern Italy near Varese and Bergamo (Lombardy) and near Bolzano, Belluno, and Udine in the Venetian provinces. Total proved reserves in all mines in 1962 were 850,000 tons of lead ore (5 to 10 percent lead) and 1,850,000 tons of zinc ore; 70 percent of the zinc reserves and 85 percent of the lead reserves are in Sardinia. Mining and processing of lead and zinc ores is mostly done by three organizations: Società Montecatini, which includes the Monteponi and Montevecchio Company; Società Mineraria e Metallurgica di Pertusola; and the government agency, Azienda Minerali Metallici Italiana (AMMI). The Montecatini organization produced about half of the country's lead and 40 percent of the zinc in 1963. Monteponi and Montevecchio operated at least six mines and seven plants in Sardinia including smelters at Monteponi and San Gavino and another at Vado Ligure near Genoa. The Vado Ligure plant, with a zinc production capacity of 12,000 tons per year, was closed in 1963 as part of Montecatini's plan to centralize metal operations at its Porto Marghera plants near Venice. Zinc production at Porto Marghera was scheduled to increase from 20,000 to 30,000 tons in 1964. Società di Pertusola operates four mines and plants in Sardinia, as well as others in northern Italy and smelters at La Spezia (lead) and Crotone (zinc). AMMI operated two mines and three plants in Sardinia, other mines in northern Italy near Bergamo and Belluno, and the Ponte Nossa zinc plant at Bergamo. At the end of 1962, total annual metal production capacity in Italy was 72,000 tons of lead and 91,000 tons of zinc. Employment in mines and plants in December 1963 was approximately 8,250.

Production of lead and zinc ores in 1963 dropped by more than 20 percent. Production of lead concentrates decreased by 15,000 tons and of zinc concentrates by 56,000 tons. The decreases were partly due to strikes in the early part of the year and also to low metal prices, but there has been a steady decline in lead ore production for several years. Rising prices in the latter months of 1963 allowed the industry to recoup some of its losses, to increase production, and to accelerate plans for reorganization. By the end of the year, a new mine (Marzio-Brusumpiano) had been opened by Miniere Riunita Varesine (MIRIVA) in northern Lombardy and another mine, near Nuoro in Sardinia, was scheduled for production in 1964 by RIMISA, a subsidiary of the Monteponi and Montevecchio Company. MIRIVA also had 12 exploration permits in Sardinia.

The decreased output of Italian mines in 1963 was accompanied by increased imports of both lead and zinc ores, and metal production was maintained at about the same level as in the previous year. Zinc production dropped by 4,000 tons or 5 percent below 1962 while lead production was practically unchanged. The total supply and consumption of both metals in Italy in 1963 was apparently not significantly changed as compared to 1962. In the latter year, lead consump-

Digitized by Google

tion was 111,000 tons, including 91,000 tons of refined lead, and consumption of zinc was 153,000 tons, including 106,000 tons of refined metal.

Exports of lead concentrate in 1963 decreased by 20 percent (1,200 tons) while exports of zinc concentrates dropped by 27,000 tons, or 40 percent as compared with 1962. Of concentrates exported in 1962 and 1963, about two-thirds of the lead and 15 to 40 percent of the zinc were reported as temporary exports, probably for smelting and refining and re-import into the country. Exports of zinc metal decreased by 85 percent to 300 tons while exports of lead were slightly increased.

Imports of lead ores in 1963 increased by 13,000 tons and were more than twice the quantity imported in 1962. Imports of lead scrap also increased slightly but the tonnage of ingots dropped by 9,000 tons and was nearly 20 percent below the 1962 level. Imports of zinc ores increased 8,000 tons, and combined imports of ingots and scrap rose about 5,000 tons. About one-fifth of the imported lead and zinc ingots were reported as temporary imports.

Because of the importance of the lead-zinc industry to the Italian economy as well as to the EEC, the Italian Government has given high priority to reorganization and development of the industry. The State minerals agency, AMMI, and the Montecatini group plan to construct three new milling plants in Sardinia with a total investment of 54 billion lire (US$86 million), of which about two-thirds will be spent by the Monteponi & Montevecchio Co. for a new smelter at San Gavino and new flotation plants at Campo Pisano and at the open-pit mine near Sos Enattos. AMMI planned to construct two new smelters, one at Porto Vesme and the other at Massua, and was conducting new explorations for lead and zinc in Sardinia as well as on the mainland. AMMI's program in 1963 also included plans for a zinc-plating plant in the Friuli-Venezia Giulia region to use the metal produced at its Ponte Nossa plant.

Magnesium.—Italian production of magnesium metal has averaged about 5,500 tons per year since 1960. With domestic consumption about 800 tons annually, approximately 80 percent of production is exported, mainly to West Germany.

Most, if not all, of this metal has been produced electrolytically from dolomite by Società Italiana per il Magnesio e Leghe di Magnesio in its plant at Bolzano. In 1963 the company began a program of modernization and extensions to the Bolzano plant which will raise productive capacity to 10,000 tons annually in 1965.

In Sardinia, the country's first plant for production of magnesium oxide from sea water was nearing completion at San Antioco near Cagliari. The plant will have a productive capacity of 50,000 tons per year and is expected to begin production in 1964. This project, costing about 10 billion lire (US$16 million), was financed by Italian, British, and German capital under the company name of SARDAMAG.

Manganese Ore.—Italy is the only producer of manganese ore (containing more than 20 percent manganese) within the European Economic Community. Annual production has remained fairly constant over the past 10 years, averaging 47,000 tons of beneficiated ore with an average manganese content of 25 to 30 percent. Although

Digitized by Google

data on its use was not available, the ore produced in 1963 would account for 75 percent of blast furnace consumption, or an estimated 25 percent of the manganese used in ferroalloy production. At the end of the year, ore stocks at the mines were 18,000 tons and employment had decreased to 134 as compared with 246 in 1959.

Almost all domestic production came from FERROMIN's Gambatesa mine, north of La Spezia. Deposits of manganiferous iron ore, with an average manganese content of 15 to 18 percent, were formerly mined near Grosseto but production was stopped in 1958.

Imports of manganese ore increased by 64,000 tons, or 62 percent more than in 1962. The apparent rise in demand was not accounted for by increased consumption in the iron and steel industry but may have been due to stock requirements or other industrial uses. In 1963, Egypt replaced Angola as the principal source of supply and imports from the Republic of the Congo (Léopoldville) tripled as compared with 1962.

Mercury.—Italy, closely followed by Spain, continued to rank first among world producers of mercury in 1963 and accounted for 23 percent of estimated world production. Although the tonnage of crude ore produced has declined each year since 1960, metal production has remained fairly constant at about 55,000 flasks. As in previous years, most mercury production came from the mines east of Grosseto which are operated by the government-controlled Società Mineraria Monte Amiata and by the private concern, Stabilimento Minerario del Siele. These two companies accounted for about 90 percent of production, from cinnabar ores containing an average mercury content of 0.5 to 0.7 percent.

Recently installed Gould furnaces at Monte Amiata's Abbadia San Salvatore mine have increased productive capacity and have raised mercury recoveries to about 95 percent as compared with 85 percent recovered by use of the older Czermak-Spirek furnaces. The Siele company was also improving mercury recovery at the Cerreto Piano mine by use of flotation. Employment in mercury mines and plants was 1,400 at yearend.

In 1962 Monte Amiata was exploring for mercury elsewhere in Italy, including Sardinia, and had purchased the Castagneto della Trinità mine 30 kilometers northwest of Rome.

Exports of mercury in 1963 were more than double those of 1962 and exceeded the year's production by 21,000 flasks. This was attributed to the higher prices obtained in the latter part of 1963 and to release of company stocks. Most of the increased deliveries went to Japan, the United Kingdom, and West Germany. The decreased level of stocks at the end of the year was expected to result in increased production during 1964.

Uranium.—Radioactive mineral investigations have been conducted in Italy by Società Minerali Radioattivi Energia Nucleare (SOMIREN), a subsidiary of AGIP Nucleare in the ENI group, and also by Società Montecatini and Società Chimica e Mineraria per l'Uranio. Most of the deposits are located in northern Italy at Val Serio (Lombardy), Val Rendena (Trentino), Val Maira (Piedmont), and in Cuneo Province, but others were reported from Lazio

Digitized by Google

(Rome area), from Calabria, and from Sardinia. None of the occurrences appear to be of economic importance.

The largest deposits were reported to occur near Novazzo in Val Serio. In 1961 SOMIREN completed more than 1,000 meters of exploratory tunnels and estimated that the deposits contain 600,000 tons of material having an average U_3O_8 content of 0.12 percent. Previously, SOMIREN had estimated that the Val Rendena concession contained 80,000 tons and the Val Maira concession contained 50,000 tons of uranium-bearing material. In 1959 Società Chimica e Mineraria per l'Uranio reportedly mined 244 tons of material containing 0.15 percent U_3O_8 from its concessions in Cuneo Province.

In 1961, AGIP Nucleare and Società Italiana Meridionale Energia Atomica (SIMEA) were constructing two research reactors near Bologna as well as the Latina nuclear powerplant south of Rome. In December 1961 a contract was signed with the United Kingdom for the purchase of nuclear fuel for the Latina plant.

Other Metals.—Italy's small production of antimony came from oxide and sulfide deposits in the Cagliari district of Sardina. Production decreased to one-fourth of the 1962 level while imports of metal increased by 200 tons.

A small amount of tungsten ore has been produced annually from the Traversella mine 50 kilometers north of Turin. The mine, operated by the Fiat company, produces concentrates of iron, sulfur (pyrite), copper, and tungsten from ore consisting largely of iron and copper sulfides. Scheelite, which constitutes 0.002 to 0.005 percent of the ore, is recovered by tabling and flotation. The ore also contains small amounts of lead, bismuth, cobalt, molybdenum, and traces of uranium. The plant is run on two shifts and has an ore capacity of 360 tons per day.

Italy imports relatively large quantities of titanium and zirconium concentrates. Imports of titanium concentrates in 1963 increased by 30,000 tons about 45 percent more than in 1962. Most of this material was probably used by the chemical industry for manufacture of titanium dioxide, production of which has risen steadily from 13,600 tons in 1956 to 35,000 tons in 1962. A small amount was probably used in ferroalloy production.

Imports of zirconium concentrate in 1963 increased by 3,600 tons, 48 percent more than in 1962. The material may have been mostly used for foundry sands or other refractory materials.

NONMETALS

Asbestos.—Although Italian production of asbestos is relatively small compared to the major producing countries, Italy ranks seventh in world production and first in Western Europe. Since 1960, annual production has been maintained at about 55,000 tons, slightly exceeding U.S. production until 1963. About two-thirds of the Italian product is made up of various short-fiber grades, about one-third is powder, and several hundred tons of long-fiber tremolite is usually produced. The bulk of 1963 production came from the Turin area and was concentrated by air-separation from an estimated 1,300,000 tons of crude ore. Long-fiber asbestos is mined near Sondrio and Aosta.

Digitized by Google

Exports in 1963 amounted to about 10 percent of production, mostly to West European countries, with the remainder consumed within the country. Imports, probably of long-fiber grades, are mostly obtained from South Africa and Canada; these imports increased from 14,000 tons in 1959 to 44,000 tons in 1961 but since then have gradually decreased.

Barite.—Production of barite in 1963 decreased by 15,000 tons and was 12 percent less than in 1962. The drop in production was accompanied by sharply reduced exports as well as decreased drilling for oil and gas in Italy during the year. Exports fell by 24,000 tons and were less than half the quantity exported during the previous year. The decline in exports was chiefly due to reduced shipments to Iran and Kuwait.

Bentonite.—Production of bentonite increased by 31,000 tons in 1963. The increased output was apparently due to higher domestic demand, although exports of this commodity increased by about 2,000 tons as compared with 1962.

Cement.—For several years, Italy has ranked fifth in world cement production and second in the EEC. In 1963 production increased 10 percent to more than 22 million tons. This was 40 percent of EEC output and an estimated 6 percent of world production. More than 99 percent of production was used within the country for construction of roads, buildings, dams, and industrial plants.

Cement production in 1963 was 40 percent greater than in 1960 and was twice the output of 1955. In 1960 there were 72 firms producing cement, with 115 plants and 224 kilns with a total rated capacity of 17,282,000 tons per year. Based on the increase in production, the industry's capacity had increased by 1963 to an estimated 24 million tons per year and plant employment had increased to about 20,000.

The cement industry is concentrated in northern Italy, particularly in the highly industrialized area between Genoa and Milan although there are numerous plants throughout the Po Valley and some large installations near Naples and Rome. In 1960, the largest plants were located at Bergamo (840,000 tons per year), Naples (800,000 tons), and Milan (580,000 tons). An estimated 50 percent of productive capacity was located in northern Italy, 20 percent each in central and southern Italy, and 10 percent in Sicily and Sardinia. It is unlikely that this distribution was radically changed in 1963 although the industrialization of southern Italy, including Sicily and Sardinia, has been a major objective of the Italian Government. The principal limestone quarries are also located in northern Italy close to the centers of cement production. The largest cement companies in 1960 were Italcementi Fabbriche Riunite Cemento (19 plants, total annual capacity of 4,345,000 tons); Unione Cementi Marchino (a subsidiary of Società Fiat) (10 plants; 1,700,000 tons); the Segni Co. (5 plants; 1,620,000 tons); and Cementerie del Tirreno (CEMENTIR) (2 plants; 1,300,000 tons). CEMENTIR is part of the government-controlled FINSIDER combine.

Construction Materials.—*Building and Ornamental Stone.*—Production of block marble in 1963 was slightly less than in 1962 and was 12 percent below the 1961 level. Data on other stone production was not available for 1962 or 1963, but total annual production (excluding

Digitized by Google

crushed stone) has averaged 20 million tons for the previous 4 years. Polished and block marble produced in 1963 was valued at an estimated US$37 million.

More than 80 types or grades of marble are produced in Italy, mostly from Tuscany, and numerous other varieties of metamorphic, igneous, or sedimentary rock are quarried in many parts of the country including Sicily and Sardinia. The most recent statistics available indicate that in 1959, the marble and building stone industry employed about 50,000 persons, including 23,600 in quarries, 23,400 in finishing shops, and 3,000 in sawing plants. At the end of that year there were 2,500 operating quarries with 676 sawing plants and 5,000 finishing shops.

In 1961 production of building and ornamental stone of all types (excluding crushed stone) was about 22 million tons, of which block marble constituted 4 percent, other dimension stone 14 percent, and rough stone 82 percent. Limestone accounted for 38 percent of total production, followed by diabase (14 percent), basalt and lava (10 percent), and marble (9 percent). The estimated value of this production was US$72 million, of which marble accounted for 44 percent, followed by limestone (10 percent), calcareous tufa (10 percent), and travertine (9 percent).

Exports of marble in blocks, slabs, and finished pieces in 1963 increased by 5 percent over those of 1962 and were valued at an estimated US$23 million. Exports of other dimension stone were valued at US$800,000. There is a substantial demand for chips, powder, and other stone waste, and exports of this material (principally marble and onyx) in 1963 were valued at US$3.7 million.

Imports of building stone have doubled since 1961, and the tonnage imported in 1963 was approximately equal to half of Italy's exports. Portuguese marble was the principal item and was valued at US$5.8 million. The only other building stone imported in appreciable quantity was granite or similar rock in unfinished blocks, mostly obtained from Norway and Sweden.

Miscellaneous Quarry Products.—In 1961 quarries produced an additional 40 million tons of crushed rock and rubble, of which more than 50 percent consisted of limestone and gypsum for industrial use. The quantity of other materials produced in quarries was 60 million tons, of which sand and gravel constituted 51 percent and clays 41 percent. The total value of crushed rock and other quarry products was estimated at US$82 million. Detailed production statistics for the quarrying industry are given in table 11.

Fertilizer Materials.—Italy's production of potash ore in 1963 increased by 20 percent as expansion of mine operations continued in the Caltanissetta and Enna areas of Sicily. With production beginning in 1957, annual output of potash ore has risen to more than 1.2 million tons. New mines under development or planned at both localities in 1963 were expected to increase annual production capacity to 2 million tons in 1966. The potash content of ore produced in 1963 was estimated at 190,000 tons.

TABLE 11.—Quarrying industry statistics

(Thousand metric tons unless otherwise specified)

Commodity	Production				Main producing centers, 1961 (in order of quantity produced)
	1958	1959	1960	1961 [1]	
Building and ornamental stone:					
Alabaster:					
Calcareous (onyx)	2	1	1	1	Trieste, Firenze, Siena.
Gypseous	5	4	8	6	Pisa.
Breccia and conglomerate:					
Cut and worked	13	12	14	14	Agrigento, Bergamo.
Other pieces	54	50	48	59	Syracuse, Messina, Genoa, Agrigento.
Calcareous tuff:					
Cut and worked	818	800	840	809	Lecce, Bari, Agrigento, Palermo.
Other pieces	867	867	1,096	882	Lecce, Taranto, Bari, Palermo, Foggia.
Diabase (pieces)	14	--------	700	3,172	Genoa.
Diorite:					
Cut and worked	8	10	8	6	Turin, Novara.
Other pieces	--------	4	5	295	Bolzano-Bozen.
Gneiss:					
Cut and worked	209	146	96	116	Novara, Cuneo, Turin.
Other pieces	3	2	2	1	Cosenza.
Granite:					
Cut and worked	77	63	67	80	Sondrio, Novara, Livorno.
Other pieces	129	105	121	27	Catanzaro, Sondrio. (Prior to 1961, Sardinia.)
Gypsum:					
Cut and worked	64	67	70	74	Agrigento, Caltanissetta, Enna.
Other pieces (for industrial use).	1,170	1,910	1,825	2,001	Ravenna, Asti, Bergamo, Bologna.
Lava:					
Cut and worked	427	454	433	413	Naples, Catania, Rome, Padua.
Other pieces	1,511	1,588	2,325	1,916	Padua, Rome, Catania, Naples.
Limestone:					
Cut and worked	678	708	816	728	Bari, Syracuse, Ragusa, Palermo, Agrigento.
Other pieces	7,190	7,806	9,705	7,845	Bergamo, Avellino, Alessandria, Bari, Rome.
For lime and cement	13,634	16,900	19,083	18,522	
Marly (for hydraulic lime)	1,275	916	860	949	Trento, Firenze, Piacenza, Como, Vicenza, Agrigento.
Crushed	9,432	11,463	15,382	13,407	[2].
Marble:					
White, in blocks	439	423	508	677	Massa-Carrara, Lucca, Brescia, Trieste, Vicenza, Verona.
Colored, in blocks	215	248	328	315	
White and colored, other pieces.	621	711	870	1,168	Bergamo, Verona, Brescia, Siena, Vicenza.
Peperino:					
Cut and worked	14	13	13	13	Rome, Viterbo.
Other pieces	92	86	81	82	
Porphyry:					
Cut and worked	112	209	183	159	Trento, Bolzano-Bozen, Varese.
Other pieces	24	28	30	30	Varese, Bolzano-Bozen, Trento, Livorno.
Quartz and quartzite:					
Cut and worked	9	8	9	11	Cuneo, Turin, Sondrio.
Other pieces	157	142	211	170	Bergamo, Grosseto, Trento, Savona.
Sandstone:					
Cut and worked	210	240	202	245	Firenze, Lecce, Livorno, Arezzo.
Other pieces	853	932	762	906	Firenze, Livorno, Arezzo, Palermo, Messina, Enna.
Schist:					
In slabs, worked	25	26	24	51	Sondrio, Valle d'Aosta.
Other pieces	5	5	1	6	Bergamo.
Serpentine:					
Cut and worked	10	--------	--------	--------	(1958: Parma 10 tons.)
In chunks and scraps	64	109	163	47	Genoa, Parma.
Slate, in sheets	51	53	58	61	Genoa, Sondrio, Bergamo.
Syenite, cut and worked	15	15	14	12	Vercelli.
Travertine:					
In blocks, worked	263	272	264	291	Siena, Rome, Ascoli-Piceno, Grosseto, Terni.
Other pieces	194	203	195	267	Rome, Viterbo, Siena, Grosseto, Terni.
Volcanic tuff:					
Cut and worked	80	101	122	117	Rome, Grosseto, Viterbo.
Other pieces	1,563	1,634	3,458	1,667	Rome, Naples, Viterbo, Latina.
Other crushed stone	4,449	4,382	7,225	5,783	Caserta, Genoa, Rome, Turin, Varese (all types).

The major producing firms in 1963 were Società Montecatini and Società Industriale Catanese (SINCAT), the latter a member of the Società Edison group. Montecatini's San Cataldo mine at Caltanissetta accounted for about two-thirds of total production. This mine is a highly mechanized underground operation, producing 3,000 tons of kainite-carnallite ore per day. Mine run ore, with an average grade of 12 percent K_2O, is concentrated by flotation to a grade of 17 percent before shipment to the company's sulfate plant at Campofranco 18 kilometers distant. The Campofranco plant, with an annual capacity of 200,000 tons of potassium sulfate, ships its product down to the coast to a fertilizer plant at Porto Empedocle.

Mine development and plant construction at Montecatini's new Palo mine at Caltanissetta were nearing completion in 1963 and production was scheduled to begin in 1964. The Pasquasia mine near Enna, owned by Società Trinacria (an Edison affiliate), was also in an advanced stage of development and produced some sylvite-carnallite ore

Digitized by Google

in 1963. Società Edison was reportedly planning to open a second sylvite mine in 1965. In other activities in 1963, two subsidiaries of the ENI group were exploring for soda, potash, iodine, and bromine in the vicinity of Gela.

With increasing domestic supplies, exports of potassium fertilizers from Italy rose about 20 percent in 1963. Imports of potash ores from European countries have generally decreased but considerable quantities of potassium chloride continued to be imported from Israel, the U.S.S.R. and Spain.

Fluorspar.—Italian fluorspar production in 1963 was 31,000 tons less than in 1962 and was the lowest since 1956. Factors contributing to this decline were higher labor and transportation costs as well as decreasing exports to the United States. Labor costs were reportedly 25 percent higher in 1963 following negotiation of a new labor contract in the preceding November. Inland freight rates and port handling charges also increased. This weakened the competitive position of Italian fluorspar, particularly in relation to Spanish and Mexican producers. Italy's production was surpassed in 1963 by Spain, which became West Europe's second largest producer.

Italy's declining exports of fluorspar to the United States, from 108,000 tons in 1959 to 35,000 tons in 1963, were attributed partly to leveling off of American stockpile purchases and partly to increased imports of Mexican fluorspar by the United States. The Mexican product was reportedly delivered to U.S. east coast ports for US$33 per ton. In 1963 Italian producers were seeking the temporary exemption from EEC tariffs that has been granted to lead-zinc and sulfur producers in Italy. It was hoped that increased demands for acid-grade fluorspar, created by Europe's expanding chemical industry, would improve the market situation.

Some changes took place in the distribution of fluorspar production in Italy during 1963. Although the Torgola mine (near Brescia) of Società Mineraria Prealpina probably remained the nation's largest single producer, an increasing share of Italian production was reported from mines of the Giulini group in Sardinia. Also, Montecatini's production of fluorspar from the Prestavel mine (north of Bolzano) amounted to 20,000 tons (7,300 tons in 1962), or 16 percent of Italian production in 1963.

Pumice.—Italy has produced a superior grade of pumice for many years, mostly from the Lipari Islands and Sicily (Messina). Italy ranks third in world production after West Germany and the United States but exported pumice principally to these two countries in 1963. Total exports in 1963 increased by more than 200,000 tons as compared with 1962.

Pyrite.—The decline in pyrite production in 1963, the first in many years, was attributed to strikes at the mines early in the year and to the shorter workweek (44 hours) incorporated in new labor contracts. Productivity increased, however, at Montecatini's Niccioleta and Gavorrano mines north of Grosseto. These mines account for about 90 percent of Italian production and have a combined productive capacity of 5,000 tons of ore per day. Until 1963, all ore was treated at the mines by flotation to obtain a high-grade pyrite concentrate before roasting. During 1963, an increasing share of Niccioleta ore was being processed at the company's new roasting plant at Follonica.

Digitized by Google

The Follonica plant produces sulfuric acid and iron concentrates from mine-run ore. Montecatini's mines at Brasso and Calceranica were reducing output in 1963 and were scheduled for shutdown in the near future. The Elba mine ceased operation in June.

Exports of pyrite in 1963 decreased 35 percent as compared with 1962, continuing a trend which started in 1960. Exports of cinder, however, increased 44,000 tons. Imports of pyrite have steadily grown over the past 5 years and increased 11 percent in 1963. Cyprus and the U.S.S.R. remained the principal suppliers.

Sulphur.—Italian production of elemental sulfur again declined in 1963, as it has for the past 10 years. Production of sulfur concentrates, while nearly triple that of 1959, increased only 5 percent and appeared to be leveling off. Of total ore production, Sicilian mines accounted for 83 percent and the remainder came from the Bologna district.

Exports of sulfur in 1963 decreased by nearly 50 percent and were less than one fifth the quantity exported in 1961. Imports were negligible in 1963, but increased domestic consumption and depletion of producers' stocks were expected to result in substantial imports of sulfur in 1964.

In Sicily, where high production costs have virtually eliminated Italian sulfur from world markets, reorganization of the industry continued. From 1956 to 1962 the number of operating mines had been reduced from nearly 200 to 50; employment was reduced 50 percent; and processing efficiency had improved. Surveys of the industry by private consultants in 1962 recommended additional cuts of about 50 percent in the number of mines and personnel, and that the ore be used directly for production of sulfuric acid. The Italian Sulfur Agency and the Sicilian Mining Board agreed that such measures were necessary, and both agencies have submitted plans for their implementation to the EEC Commission. It was expected that EEC tariff protection, accorded to the industry since 1960, would be extended through 1964.

Talc and Steatite.—Production of talc and steatite in 1963 was about 25 percent greater than in 1959. Italy's production was about 5 percent of world output and was second to that of France in western Europe. The industry employed at least 900 persons at the end of the year.

Most of production came from the Turin area (principally the Fontane mine), but substantial quantities were also produced near Sondrio and in two districts of Sardinia. The products are generally of high quality. Società Talco e Grafite Val Chisone was the principal producing firm, with plants at Malanaggio and Livorno.

For the past 6 years, exports have amounted to 35 to 50 percent of production, with the principal buyers being the United States, United Kingdom, and West Germany. Imports, mostly from Austria, have risen from less than 2,000 tons in 1959 to more than 13,000 tons in 1963.

MINERAL FUELS

Italy's main domestic energy resources are hydroelectric power and natural gas. Other domestic energy resources include coal, lignite, petroleum, and volcanic steam; these are locally important but do not contribute substantially to the total energy supply. About two-thirds of all energy produced in Italy in 1963 was derived from solid and liquid fuels, most of which were imported. Eighty-five percent of Italy's solid fuel supplies and more than 97 percent of the petroleum were obtained from foreign sources. Total energy consumption in Italy has increased about 12 percent annually since 1950.

The proportion of total energy requirements supplied by petroleum has steadily increased and this trend was expected to continue. Petroleum fuels provided an estimated 56 percent of Italian energy requirements in 1963, followed in importance by hydroelectric power, solid fuels, and natural gas. Despite increased construction of hydroelectric plants and mounting consumption of solid and gaseous fuels, the relative proportions of total energy requirements supplied by these sources declined.

About 66 percent of Italy's electric power was of hydroelectric origin in 1963. Of the 34 percent of total supplied by thermal plants, almost six-tenths was derived from liquid fuel in 1963. Consumption of all mineral fuels was expected to increase, as the total generating capacity of thermoelectric plants under construction in 1963 was twice the capacity of the installations available in 1962.

Three nuclear powerplants were in advanced stages of construction in 1963. The Latina and Garigliano plants, located near Rome and Naples, respectively, were operated briefly during the year and produced over 300 million kilowatt-hours of electricity. The third plant, located on the Po River (Trino Vercellese) east of Turin, was scheduled for preliminary operation in 1964.

Coal.—Coal production in 1963 declined 15 percent as compared with 1962, apparently due to relatively high costs of domestic production as well as to increased imports of higher grade coal.

Most of Italy's coal deposits are of subbituminous grade and are in Sardinia. The small annual production of anthracite has come mostly from La Thuile near Aosta in the Western Piedmont. Sardinian (Sulcis) coal constitutes about 95 percent of Italian production

Sources: Ente per l'Energia Elettrica (ENEL) reports, through U.S. Department of State dispatches. Associazone Nazionale Imprese Produttrici e Distributrici di Energia Elettrica (ANIDEL) (Rome). L'Industria Elettrica Italiana nel 1962. 1963, 161 pp.

and is largely used for fuel in thermal powerplants. Italian coal reserves in 1963 were estimated to be 500 million tons of Sulcis coal and 2.5 million tons of anthracite.

Because of a relatively low-quality product and high production costs, the Sardinian coal industry has experienced difficulties similar to those of the sulfur industry in Sicily. With many small mines, rising labor cost and (until 1963) the lowest output per man-shift in EEC, the industry has not been able to compete with foreign producers. Production in 1963 was about 60 percent of the 1953 level and employment in mines and plants decreased from about 7,000 to about 2,200 during the same period. Under a modernization program begun several years ago, high-cost mines have been eliminated and mechanization has been increased so that the output of coal per man-shift in 1963 was more than tripled compared with 1953. In addition, Società Mineraria Carbonifera Sarda (CARBOSARDA), owned by the Italian National Power Agency (ENEL), was completing construction of a large thermoelectric plant at Porto Vesme. The plant will be fueled by mine-run coal from local mines. CARBOSARDA also announced that mechanization of the Seruci mine will be completed by mid-1964 and that new facilities at the Nuraxi Figus mine were also nearing completion. By the end of 1964, the government anticipates a total annual production of 2.4 million tons of coal from these mines. This quantity would be equivalent to more than four times the Sardinian production in 1963.

Exports of coal from Italy have been negligible compared to the total supply although there were increased shipments to France in 1963. Exports of coal were valued at US$480,000.

Imports of coal in 1963 exceeded 11 million tons for the first time and were valued at approximately US$160 million. The total tonnage was 4 percent more than in 1962, and the increase was mainly due to anthracite imports, which rose by 320,000 tons. Coking coal made up 53 percent of all coal imports, followed by steam coal (18 percent), gas

Digitized by Google

coal (17 percent), anthracite (11 percent), and coal agglomerates (1 percent). Imports from the United States increased 1.8 million tons and were 33 percent more than in 1962, whereas imports from ECSC countries (principally West Germany) fell by 1.1 million tons, or 36 percent. Imports from East European countries also declined, principally from Poland and Czechoslovakia, although imports from the U.S.S.R. (mostly anthracite) rose 140,000 tons. The United States supplied 60 percent of Italy's coal imports in 1963 as compared with 47 percent in the previous year.

More than 50 percent of Italy's coal supply in 1963 was used for making coke. An estimated 17 percent was used for domestic and commercial heating, 10 percent for gasworks, 6 percent for the transportation and construction materials industries, and 3 percent for thermoelectric power. Consumption of coking coal was expected to increase, whereas steam and gas coal were encountering increased competition from liquid and gaseous fuels.

Production of liquid coal-derivatives continued to increase in 1963 although at a reduced rate as compared with previous years. Production in 1963 was 30 percent more than in 1959. Apparent domestic consumption of these products increased as exports were negligible and imports rose by one-third.

Coke.—Total coke production in 1963 was about 2 percent higher than in 1962, with increased production of metallurgical coke being offset by lowered production in gasworks. All coking coal was imported, with the United States supplying 86 percent. Exports of coke, usually destined for Austria and Switzerland, dropped 14 percent while imports of coke more than doubled. Consumption of metallurgical coke in the iron and steel industry was about 2.6 million tons of which 90 percent was used for pig iron production and 5 percent in agglomerating plants.

Lignite.—Lignite production in 1963 declined by 23 percent because of reduced demand from thermoelectric plants. All lignite produced was of the xyloid or lower-grade type, having a calorific value of about 2,500 calories per gram. Production of "Picean" or high-grade lignite (calorific value about 4,300 calories per gram), became so uneconomical that none was produced in 1963.

Italy's principal lignite deposits are located near Perugia and Arezzo in central Italy (Umbria and Tuscany) and in southern Italy (Calabria and Basilicata). The Picean lignite mostly came from the Grosseto area in west Tuscany. Total proved reserves of lignite in 1963 were estimated to be about 150 million tons.

Prior to 1958 most lignite produced was used in manufacturing construction materials (mostly tiles), but since that year its principal use has been fuel for thermoelectric powerplants constructed near the deposits and production has greatly increased. More than 95 percent of the lignite produced in 1962 was used for power generation and accounted for about 9 percent of Italy's thermoelectric power. In 1963 a new powerplant was being constructed near lignite deposits at Laino Borgo (near the Calabria-Basilicata boundary) by Società Meridionale di Elettricità. At the end of the year a total of 700 workers were employed in lignite mines as compared with 2,200 in 1958.

Digitized by Google

No exports of lignite were reported during the past 2 years. Imports of lignite in 1963, mostly briquets obtained from West Germany, increased 52,000 tons, or 20 percent as compared with 1962.

Petroleum and Natural Gas.—The oil and gas industry ranks with the iron and steel industry as one of the major mineral industries of Italy. Although only about 12 percent of Italy's energy requirements are produced from domestic resources of oil and gas, the industry provides two-thirds of the total energy supply by importing and refining large quantities of crude petroleum. Italy processed more crude oil in 1963 than any other country in the EEC and was second only to the United Kingdom in Western Europe. Output of refinery products in 1962 amounted to 18 percent of West European production and 3.4 percent of world production.

The growth of the processing industry is comparable to that shown by iron and steel, and productive capacity has doubled during the past 5 years. Imports of crude petroleum, refinery production, and domestic consumption of petroleum products have shown annual increases of 10 to 20 percent. In 1963, investments in the oil and gas industry were estimated at US$350 million, and six petrochemical plants completed or under construction represented a total investment estimated at US$1 billion. In 1962 and 1963 the petroleum industry provided about 14 percent of all government revenue, largely from sales of petroleum products.

Although small by world standards, discoveries of oil in Sicily and of gas in northern Italy since 1953 have been important in the country's industrial development. Italy's production of natural gas, until recently the largest in Western Europe, is mostly used for industrial fuel and is distributed by some 6,000 kilometers of pipelines. The petroleum and gas deposits in Sicily will be further exploited by a large petrochemicals complex at Gela which was nearly completed in 1963.

Within the EEC, Italy's gas reserves rank third after The Netherlands and France, and its recoverable reserves of petroleum rank second after West Germany. Although small discoveries of oil and gas continued to be made in 1963 and there was increased interest in Adriatic marine areas, the limited success of exploration drilling and a decline of 25 percent in all drilling activity since 1960 suggests that major new discoveries of oil or gas are unlikely and that Italy's rising demand for energy will be met by increased imports of fuel.

Government Participation.—The largest firm in Italy's oil and gas industry is the government-owned Ente Nazionale Idrocarburi (ENI). ENI was established in 1953 with authorization to participate in all sectors of the oil and gas industry and was given exclusive oil and gas rights to most of the Po Valley. The Po Valley concession extends from the Adriatic Sea west to Rivoli and Cuneo in the Piedmont, and includes Adriatic coastal waters for a distance of 15 kilometers offshore between Rimini and Monfalcone. ENI also holds numerous concessions in the oil- and gas-producing areas of central and southern Italy as well as in Sicily.

The principal divisions of ENI are: Azienda Generale Italiana Petroli (AGIP) Mineraria (exploration and production); Società Nazionale Metanodotti (SNAM) (transport and distribution of nat-

Digitized by Google

ural gas); AGIP (transport, refining, and marketing of petroleum products); Azienda Nazionale Idrogenazione Combustibili (ANIC) (petrochemicals and refining); and AGIP Nucleare (nuclear energy). Through these divisions and about 80 other partly- or wholly-owned companies, ENI conducts its domestic operations and is heavily engaged in petroleum exploration, production, refining, engineering, or products distribution in many foreign countries. The organization's engineering and construction projects both in Italy and abroad are usually handled by Nuovo Pignone and SNAM Progetti. Total sales of the ENI Group in 1963 were about US$965 million, and Italian employees were estimated to be 35,000.

Exploration and Development.—Drilling activity in Italy continued to decline in 1963. Total depth of all wells drilled during the year (including gas wells) was about 316,000 meters as compared with 366,000 meters in 1962. Exploration drilling was only slightly less than in 1962 but development drilling decreased by nearly 40 percent. Oil was reportedly found in two exploration wells—one near Parma and the other near Foggia—but its commercial significance appeared to be slight. In development drilling, AGIP Mineraria completed six oil wells in the Gela field, four of which were drilled offshore from a fixed platform and one was deviated seaward from shore. Production from the Gela field was expected to increase substantially in 1964 as ANIC's petrochemical plant was scheduled to begin production early in the year. In central and southern Italy, oil was produced from several development wells which had been drilled for gas. Società Nazionale Industria Applicazioni Viscosa (SNIA Viscosa) found oil in two wells drilled to develop the Candela gasfield, and Società Ricerche Idrocarburi (SORI) reported 26° API gravity oil in two wells drilled to develop a gasfield discovered northwest of Foggia. In the San Cataldo oilfield, Società Ricerche Petrolifere Meridionale (RPM) completed one development well.

The area held under petroleum concessions in 1963 declined 10 percent as compared with 1962. Increased interest in offshore exploration in the Adriatic Sea was evident from a threefold increase in the total area covered by applications for offshore concessions. In contrast, the total area of land concessions applied for in 1963 decreased 45 percent from the previous year. Most of the interest in offshore exploration appeared to be in the regions of Veneto, Emilia-Romagna, and Marches.

In foreign operations, ENI continued its exploration and development activities, particularly in Iran and Egypt. In Iran, two development wells were completed in the offshore Bahrgansar field and another well was drilling at the end of the year. Six wells were producing by December 31. Production from this field in 1963 averaged about 14,800 barrels of oil per day, as compared with 6,200 barrels per day in 1962. The Bahrgansar field is operated by Société Irano-Italienne des Pétroles (SIRIP) in which ownership is shared equally by AGIP Mineraria and the National Iranian Oil Co. The company's export terminal was completed in 1963 and production was scheduled to increase during 1964.

The ENI affiliate in Egypt, Compagnie Orientale des Pétroles d'Egypte (COPE), increased production by more than 20 percent to

Digitized by Google

about 86,000 barrels per day. The rise in output was mainly due to a fivefold increase in production from the Marine Belayim field. COPE's output accounted for 75 percent of total Egyptian production during 1963. The company is owned 50 percent by ENI.

Unsuccessful exploration wells were drilled in Libya, Morocco, and the Sudan. AGIP Mineraria's explorations in Somalia were reportedly suspended, but surveys were continuing in Libya, Morocco, and the Sudan as well as in Iran, Nigeria, and Tunisia. In India, ENI began drilling an exploratory well in Bihar to explore Tertiary formations. The well was spudded in October and was still drilling at the end of the year.

Ausonia Mineraria, an affiliate of the Società Edison, reportedly drilled two exploratory wells in Lebanon in 1963 with negative results. The wells were drilled on concessions of Cie. Libanaise des Pétroles, one at Suhmur and the other at Tel Znoub. Ausonia Mineraria also has interests in concessions in Algeria and Libya.

The Genoa-Aigle segment of the Central European pipeline was completed in mid-1963 by SNAM Progetti and in September began supplying oil to the new Aigle refinery. The pipeline was to be extended to Ingolstadt where another refinery was under construction. SNAM Progetti was also engaged in construction of the 1,140-kilometer Barauni-Calcutta-New Delhi oil pipeline in India and a 270-kilometer pipeline in Spain.

In August 1963, a consortium of private oil companies and the Austrian National Oil Co. announced its decision to construct a 40-inch oil pipeline from a northern Adriatic port (possibly Trieste) to Austria and southern Germany. Completion of the pipeline was planned for 1967. Throughput capacity of the pipeline was expected to reach 800,000 barrels per day from an initial rate of about 350,000 barrels per day.

Crude Oil Production.—Production of crude petroleum in Italy in 1963 was slightly less than in 1962 and was about 9 percent below the 1961 level. Total production averaged about 33,000 barrels per day, or 3 percent of Italy's supply of crude during 1963. Of total production, 96 percent came from Sicily, 3 percent from the Po Valley, and 1 percent from central and southern Italy.

In Sicily, Gulf Italia's Ragusa field continued to provide most of Italian production and accounted for 63 percent of the total output, followed by ENI's Gela field with 33 percent. Po Valley production was mostly derived from the Piacenza area. Producing wells at the end of the year included 48 at Ragusa, 71 at Gela, and 356 in northern and central Italy of which more than 90 percent were located in the Piacenza-Parma area. At the beginning of 1963, Italy's petroleum reserves were estimated at approximately 300 million barrels.

Crude Oil Trade.—Italy imports large quantities of crude petroleum to supply the refining and petrochemical industries, and exports of crude are normally insignificant when compared to the total domestic supply. Exports in 1963 represented about 0.3 percent of the domestic supply and were valued at an estimated US$2.2 million. The quantity exported in 1963 was nearly 50 percent less than in 1962 and was more than 60 percent below the level of 1961.

Digitized by Google

Imports of crude petroleum in 1963 totaled more than 47 million metric tons and were valued at an estimated US$665 million. The quantity was 15 percent greater than in 1962 and 39 percent more than in 1961. The main regional sources of supply were the Middle East (69 percent), North Africa (14 percent), and the U.S.S.R. (14 percent). As in 1962, the principal supplying country was Kuwait with 29 percent of total imports, followed by Iraq (20 percent), Saudi Arabia (17 percent), the U.S.S.R. (14 percent). These proportions were not significantly changed from 1962, although Iraq provided 27 percent of Italy's crude in 1961. Imports from Libya have steadily increased, from less than 1 percent of Italy's imports in 1961 to 6 percent in 1963. About 20 percent of all crude petroleum imported by Italy is temporarily imported, probably for refining and re-export under Italian and foreign accounts.

The total supply of crude petroleum in Italy in 1963, as calculated from net imports, domestic production, and stocks reported at the beginning of the year, was approximately 50.5 million metric tons. Of this total, an estimated 94 percent was processed by refineries and 3 percent by petrochemical plants. An additional 3 percent remained in stocks at the end of the year.

In 1963, new supply agreements were negotiated by ENI with the Standard Oil Co. of New Jersey and with the U.S.S.R. Standard Oil will supply 12 million metric tons of crude over a period of 5 years, and the U.S.S.R. will supply about 25 million tons of crude over a 7-year period. The quantity of crude to be imported from the U.S.S.R. under the new ENI agreement represents an increase of about 30 percent on an annual basis from the previous agreement for 1961–65 which called for a total of 12 million tons.[5] The Soviet oil is to be exchanged for oil industry equipment, fertilizers, synthetic rubber, and other Italian products. A third supply agreement was being negotiated with the Gulf Oil Corp. at the end of the year.

For the past several years, about 75 to 80 percent of the currency requirements for the large imports of crude petroleum were reportedly obtained from exports of refinery products, processing on behalf of foreign companies, charter of Italian tankers (Italy had 4 percent of world tanker capacity in 1963), and purchase of Italian goods and services by international oil companies.

Refined products output, consumption and trade.—The quantity of crude petroleum processed by Italian refineries and petrochemical plants in 1963 was approximately 48.5 million metric tons and was the largest quantity processed among the EEC countries. Italy produced 27 percent of the refinery products produced by the Community in 1963 and has been the leading producer since 1962. Although total production of refinery products was exceeded by the United Kingdom, Italy's refinery capacity was the largest in Western Europe. An estimated 39 refineries and 31 petrochemical plants were operating in Italy at the end of 1963.

Most petroleum refining, petrochemicals manufacture, and distribution of petroleum products in Italy is conducted by private firms

[5] Annual imports of Soviet crude from 1961 through 1963 averaged about 6 million tons because of transactions by private firms, independent of the ENI agreement.

Digitized by Google

but about 25 percent of the industry is directly controlled by the government through the ANIC and AGIP divisions of ENI. ANIC and AGIP are the principal Italian firms engaged in refining and distribution of petroleum products in foreign countries and are particularly active in Africa and Western Europe. In Italy, the principal refining companies affiliated with ENI in 1962 were Industria Petrolifera (STANIC), owned 50 percent by the Standard Oil Co. of New Jersey, and Industria Raffinazione Oli Minerali (IROM), owned 49 percent by British Petroleum.

Italian refinieries are required to maintain a reserve capacity of at least 30 percent of authorized capacity. The reserve capacity is not usually included in published data concerning productive capacity of Italian refineries, such as those listed in table 15; the capacities listed refer only to authorized capacity. The maximum refining capacity of the industry at the end of 1962 was thus 30 percent more than the table would indicate, or about 73 million tons. By the end of 1963, the maximum figure had risen to approximately 82 million tons.

An Italian law of 1961 requires that a 56-day supply of petroleum be kept in constant reserve. Four-fifths of the required reserve is stored at refineries and the remainder is stored in commercial storage installations. The quantity of required reserves is based on the average daily consumption in Italy during the previous year. Because of rapidly rising petroleum consumption, storage requirements are increasing at the rate of several million barrels per year.

In early 1961, the Government's Interministerial Price Committee lowered the ceiling price of regular gasoline to 96 lire per liter. This ceiling has been maintained as an anti-inflationary measure. The refining industry contends that the ceiling should be either removed or readjusted to compensate for increased costs of production and marketing, but no such action appeared to be likely and the ceiling was still in effect at the end of 1963.

Output of refinery products in 1963 increased by 48 million barrels, 16 percent more than in 1962. This continued the trend of the past 5 years, during which annual refinery production has increased by an average of 19 percent. The main refinery products continued to be fuel oils and gasoline, with the former accounting for 68 percent of the total Italian production and 24 percent of EEC output. Total Italian production in 1963 was estimated to be about 80 percent of authorized refinery capacity.

Consumption of petroleum products in 1963 also increased 16 percent as compared with the previous year. Domestic consumption was estimated at 32.3 million metric tons. Consumption of motor gasoline increased by 21 percent (800,000 tons), fuel oil (excluding bunkers) by 16 percent (2.7 million tons), and gas oil by 12 percent (400,000 tons).

In 1963 the Montecatini Co. formed a partnership with the Royal Dutch Shell Group. The new company (Monteshell) took over Montecatini's large petrochemical plants at Ferrara and Brindisi. Crude oil processed by these two plants totaled about 1.5 million tons annually.

Sources: Ministero dell' Industria e del Commercio (Rome). Bollettino Petrolifero. 6th year, No. 12, December 1963, 68 pp.
Bureau of Mines. World Petroleum Statistics. Annual summaries for 1959–62.

In the distribution of petroleum products, the principal development in 1963 was the acquisition of APIR (Azienda Petroli Italiana Roma), a subsidiary of Società Fiat, by the Gulf Oil Corp. The APIR facilities, now under the name of Gulf Italiana, included 636 filling stations, coastal terminals at Livorno and Porto Marghera, and 4 inland bulk plants. Gulf has no refinery in Italy and was not previously engaged in the marketing field although the company's other Italian subsidiary, Gulf Italia, has produced most of Italy's crude petroleum from the Ragusa field in Sicily.

Exports of petroleum products from Italy in 1963 increased 7 million barrels, 12 percent more than in 1962. The exports amounted to about 20 percent of Italy's refinery production and were valued at US$270 million. Exports of distillate fuel oil increased by 5 million barrels and made up 44 percent of all product exports, followed by residual fuel oil (25 percent) and gasoline (22 percent).

Imports of petroleum products in 1963 increased 11 percent and were valued at US$75 million. Residual fuel oil made up 80 percent of the total. Imports of lubricants, principally obtained from the United States, increased by 25 percent.

Refinery Construction in Italy.—Three new refineries were under construction in Italy in 1963 and the capacity of several others was being increased. ANIC's San Nazzaro refinery at Pavia in northern Italy was scheduled for completion in 1964. The refinery will have a capacity of 80,000 barrels per day and will be fed from the Central European pipeline. Also, construction of ANIC's Gela refinery (capacity 55,000 barrels per day) was nearing completion at the end of the year. In Sardinia, a refinery at Sarroch, with a capacity of 75,000 barrels per day, was scheduled for completion in late 1964. Major extensions to present refineries at Trieste, La Spezia, and Trecate in

Digitized by Google

northern Italy and at Milazzo and Augusta in Sicily were also underway.

Refinery Construction in Foreign Countries.—ENI completed construction of three refineries in 1963 and four others were planned or under construction. The Aigle refinery in Switzerland, owned by Raffineries du Rhone, S.A., was completed by SNAM Progetti. The plant has a capacity of 45,000 barrels per day and is partly owned by ENI.

In Ghana, ENI completed the Tema refinery. This plant, which has a capacity of 25,000 barrels per day and cost an estimated US$20 million, is operated by the Ghanaian Italian Petroleum Co., Ltd. The operation is owned 100 percent by ENI but a 50 percent share will be acquired by the Ghanaian Government after 10 years.

Tunisia's first refinery was completed at Bizerte by SNAM Progetti. The plant has a capacity of 20,000 barrels per day and cost an estimated US$22 million. It is operated by Société Tuniso-Italienne de Raffinage (STIR), which is owned 50 percent by ENI and 50 percent by the Tunisian Government.

In West Germany, SNAM Progetti continued construction of a refinery at Ingolstadt for Südpetrol A.G., für Erdölwirtschaft (owned 74 percent by ENI). The refinery will have a capacity of 40,000 barrels per day and is scheduled for completion in 1964. The plant, to be operated by Erdölraffinerie Ingolstadt A.G., will be fed by the Central European pipeline.

In the Congo, Société Congo-Italienne de Raffinage (SOCIR), owned jointly by the Congolese Government and ANIC, was constructing a 12,000-barrel-per-day refinery at Léopoldville.

In Tanganyika, ENI planned to construct a refinery at Dar-es-Salaam with a capacity of 12,000 barrels per day. The Tanganyika Government will have option on a 50-percent share in the operation.

In Yugoslavia, SNAM Progetti was awarded a contract to build a 20,000-barrel-per-day refinery near Belgrade.

In Morocco, Société Anonyme Marocaine Italienne de Raffinage (SAMIR), owned 50 percent by ENI, was operating the Mohammedia refinery which was completed late in 1961. The refinery has a capacity of 25,000 barrels per day.

Natural Gas.—Production of natural gas in 1963 increased 1.6 percent as compared with 1962. Ninety-eight percent of total production came from the Po Valley region, principally from the provinces of Emilia-Romagna and Lombardy. The main producing centers were Ravenna, Bologna, Piacenza, and Cremona. Gasfields in the Abruzzo-Molise region of the Adriatic coast accounted for an additional 1.2 percent and the remainder came mostly from the Gagliano field in Sicily.

Italy's gas production in 1963 came from 1,565 wells, of which more than half were located in Emilia-Romagna. About 44 percent of the producing wells yielded wet gas. The relatively large number of producing wells (2,679 in 1960) reflects the scattered pattern of gas pools in northern Italy. In 1963 there were 53 gasfields in the Po Basin (including offshore fields in the Adriatic Sea), of which 22 were classed as important fields. Total proved reserves of natural gas in 1963 were estimated to be 140 billion cubic meters.

Digitized by Google

Exploration drilling in 1963 brought in an estimated 11 new gas wells, of which one was in the offshore region of the Po Basin, eight were in peninsular Italy in Abruzzo-Molise and Puglia Provinces, and two were in Sicily. Seven of the wells were drilled by AGIP Mineraria and four by private concerns.

In the Po Basin an offshore well drilled by AGIP Mineraria near Ravenna found gas in Pliocene strata in five zones at depths of 2,250 to 2,600 meters. The field was discovered a few kilometers south of the Ravenna Mare gasfield but appeared to be of minor importance. A second offshore well, drilled about 20 kilometers farther south, was unsuccessful as were 19 land exploration wells drilled in the Po Valley between Ravenna and Turin. AGIP Mineraria also completed two development wells in the Ravenna Mare gasfield which was discovered in 1962.

In peninsular Italy, most of the gas discoveries in 1963 were made in the San Salvo-Guglionese area northwest of Foggia. Several discoveries had been made in the Foggia region in 1962 by AGIP Mineraria (Guglionese field), Società Montecatini (Ascoli Satriano field), and by SNIA Viscosa (Candela field). All of the 1963 discoveries were made in Miocene or Pliocene strata at depths between 960 and 2,200 meters. AGIP Mineraria drilled one discovery well only 4 kilometers from Foggia and other wells in the vicinity of Ascoli Satriano. Both Montecatini and Ausonia Mineraria drilled discovery wells within 4 kilometers of AGIP Mineraria's Guglionese field, and SORI found gas 50 kilometers northwest of Foggia. Of about 30 unsuccessful exploration wells drilled between Marches and the Gulf of Taranto, five were drilled to depths between 3,400 and 5,000 meters. In development drilling, SNIA Viscosa successfully completed nine wells in the Candela field and the company estimated recoverable reserves of gas to be approximately 10 billion cubic meters. Montecatini completed two development wells in the Lentella field; Ausonia Mineraria and SORI each drilled two successful wells near their 1963 discoveries and AGIP Mineraria continued to develop the Guglionese field.

In Sicily, two of four wells drilled by ENI companies yielded dry gas and condensate. The wells were drilled to test extensions of the Gagliano reservoir formation. In the Gagliano field, 5 development wells were also completed, increasing the number of producing wells to 13.

A 270-kilometer gas pipeline from AGIP Mineraria's San Salvo field in Abruzzo-Molise to Pescara, Terni, and Rome was nearly completed by the end of 1963. The pipeline will supply gas to industrial consumers in Pescara, Rieti, and Terni, as well as to domestic consumers in Rome. The delivery rate of gas to Rome was scheduled to be 100,000 cubic meters daily by early 1964, increasing to 250,000 cubic meters in late 1964 and to 500,000 cubic meters in 1965. The pipeline was constructed by ENI's affiliate, SNAM Progetti. Two other gas pipelines were under construction by the same company in 1962 and may have been completed in 1963. These were the Ferrandini-Bari-Monopoli pipeline in Puglia and the Gagliano-Gela pipeline in Sicily. Completion of these projects was expected to increase the total length of ENI pipelines in Italy to approximately 5,000

Digitized by Google

kilometers. In Argentina, SNAM Progetti was also constructing a 1,700-kilometer gas pipeline from Santa Cruz to Buenos Aires.

In 1963 Westates-Italia Co., a subsidiary of Westates Petroleum of California, purchased a 49-percent interest in the permits and concessions of Ausonia Mineraria. Westates will furnish US$9.3 million for exploitation and development costs in connection with Ausonia Mineraria's recently discovered gas deposits northeast of Foggia. The agreement also gave Westates a share in other Ausonia concessions in Italy as well as in Libya and Algeria.

The proportion of total natural gas production consumed in various industrial sectors in 1963 was not appreciably changed from previous years although statistics were available only for the first 8 months of the year. The proportion used for heating and domestic purposes, however, appeared to have increased from 13 percent in 1961 to 23 percent in 1963. This was probably due to improved distribution facilities as well as to increased production.

The use of natural gas for petrochemical conversion was being encouraged by ENI which was offering gas for this purpose at one-third of its price for fuel. At least four petrochemical plants were using gas as raw materials in 1963.

Natural gasoline.—Production of natural gasoline condensate has remained relatively constant for the last 5 years. Production in 1963 amounted to 55,067 metric tons and was almost unchanged from 1962. Approximately 90 percent of production came from the Po Valley, mainly from Piacenza and Modena in the Province of Emilia-Romagna, and the remainder was produced in Sicily.

The Mineral Industry of Luxembourg

By Anton W. T. Wei[1]

MINERAL significance of Luxembourg lies solely in the iron and steel industry. Luxembourg, one of the smallest countries in the world, is by far the smallest member State of the European Economic Community both in population (325,000) and in area (2,590 square kilometers). Nevertheless, its steel production represents more than 1 percent of the world total and about 5.5 percent of that of the European Coal and Steel Community (ECSC). In 1963, per capita output was 12.6 tons, highest in the world. A large part of the world significance of Luxembourg derives from the country's position as an exporter of iron and steel. In this connection, the Belgium-Luxembourg Economic Union has held the leading position in the world for years, and 28 percent of the Union exports originated in Luxembourg in 1963.

Despite recent attempts to diversify the industrial base, the iron and steel industry continues to remain the preponderant element of economic life. The comment by a Luxembourg economist that "Luxembourg is a gift of iron as Egypt is a gift of the Nile" summarizes the dominant position of the industry in the economy of the country. In 1963 the iron and steel industry was responsible for nearly 75 percent of the value of industrial production, provided 65 percent of the industrial salaries, absorbed more than 80 percent of industrial investments, employed nearly 50 percent of the labor force, and furnished nearly 80 percent of the value of total exports. If the personal income taxes of employees are included, it is estimated that nearly 50 percent of the national tax revenue is derived from iron and steel activity.

SOURCE MATERIAL

Production data for the mineral industry have been obtained from foreign service dispatches of the U.S. Embassy in Luxembourg. Salient statistics about the iron and steel industry were taken from Siderurgie of the Office Statistique of des Communautés Européennes. Data and information about energy sources are derived from Charbon et Autres Sources D'energie, a publication from the same office. Information on significant developments in the industry was provided almost entirely by the iron and steel report from the U.S. Embassy in Luxembourg.

PRODUCTION

In 1963, the mineral and metal production of Luxembourg increased slightly from that of 1962. The estimated total value of output was

[1] Physical scientist, Division of International Activities.

Digitized by Google

approximately the equivalent of US$400 million, with more than 95 percent being derived from 4 million tons of iron and steel, the only metallic mineral commodities produced in the country. Other than iron and steel, 1963 mineral output consisted, as in the past, almost entirely of construction materials. Luxembourg does not produce or process any mineral fuels.

TABLE 1.—Production of metals and minerals

(Thousand metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

[1] Estimate.
[2] Data not available.

TRADE

All foreign trade statistics of Luxembourg are integrated with those of Belgium under the Belgium-Luxembourg Economic Union (see Belgium). Except for steel exports, the Luxembourg share of total trade is minor.

Following the pattern of previous years, nearly 94 percent of the finished steel output was exported. The steel trade is highly ECSC-oriented; in 1963, 66 percent of the exports went to this market.

Both imports and exports of iron ore decreased. The decline in imports from 7.3 million tons in 1962 to 6.5 million tons in 1963 was the result of strikes in French mines which normally supply practically all of the Luxembourg foreign iron ore requirements. Iron ore exports dropped below the 1 million ton mark (919,000 tons) for the first time since 1950. The Belgium market, which normally receives more than 80 percent of the iron ore exports of Luxembourg, was looking more and more to oversea sources for the supply of richer iron ores.

COMMODITY REVIEW

METALS

The Luxembourg iron and steel industry entered a period of resurgence in 1963, operating at 92 percent of capacity after undergoing a period of stagnation in 1962. New investments during 1963 were the equivalent of nearly US$44 million, compared with US$39 million in 1962 and US$36 million in 1961. The industry continued to emphasize technological improvements to raise efficiency. Production of crude steel exceeded the 4 million ton level for the 4th consecutive year but remained below the record 4.1 million tons produced in 1961.

Digitized by Google

Iron ore production showed a 7.4 percent increase, and domestic output again exceeded imports after the temporary reversal of 1962.

As of 1963, the Luxembourg steel complex, comprising three companies, consisted of 33 blast furnaces, 7 steel works, and 7 rolling mills. About 59 percent of the steel output was provided by the Aciéries Réunies de Burbach-Eich-Dudelange (Arbed) S.A., 31 percent by Hadir Hauts Fourneaux et Aciéries de Differdange-St. Ingbert-Rumelange Société Anonyme, and 10 percent by Société Minière et Metallurgique de Rodange.

[3] Output in part may consist of further processing of Luxembourg-produced semifinished products.
[4] Estimate.

Arbed completed in 1963 the construction of a 16,000 kilowatt powerplant, a sheet steel soaking pit, and a 12-ton electric furnace. Sched-

Digitized by Google

uled for completion in 1964 were three soaking pits; a 70-ton LD–AC converter; a new rolling mill; and a 7.2 meter, 700-ton capacity blast furnace. Orders were placed for a new LD–AC complex at a reported cost of US$16 million, which included two 120-ton LD–AC converters, a 1,800-ton hot metal mixer, and a new rolling mill. LD–AC refers to a two-slag process using powdered lime injected with the stream of oxygen for high-phosphorus application in the regular LD (Linz-Donawitz) converter. The OCP (Oxygène Chaux Pulvérisée) process was developed by a Belgium metallurgical research body and brought to commercial success at the Dudelange works of Arbed and has since been styled LD–AC process. In addition to these new installations, replacement of a pre-World War I blast furnace was underway at Belval. The new furnace, scheduled for completion in 1965, will have an 8-meter diameter and a capacity of 1,000 tons of pig iron a day.

Hadir completed construction of a new blooming mill. Scheduled for completion in 1964 were an 8-meter blast furnace (1,000 tons of pig iron per day) to replace an older unit, and installation of stands and motors in the new Grey mill. The long term program of Hadir's contemplates systematic replacement of all the blast furnaces of the company. During 1963 the company converted fully to the use of sintered ore for blast-furnace feed.

Rodange continued construction of the direct oxygen line from the Oxylor plant in France during 1963. The company also scheduled modest investments for 1964–65 as part of a 10-year plan to reorient its production to specialized steels based on small (25 ton) LD–AC converters.

Despite an overall increase of employment in the iron and steel industry, employment at the mines dropped about 5 percent to roughly 1,800 workers; two mines were closed during the year. In the meantime, investments continued in conveyor belts, precrushing equipment, and other facilities. Reserves in the mines were estimated to total 242 million tons of ore with about 27 percent Fe. At the existing exploitation rate, these reserves (2.6 percent of the ECSC known total) were expected to last more than 30 years.

While heartened by improvements in 1963, steel industry officials expressed concern over the prospect of adapting to conditions of ECSC on capacity. Recognizing no quick solution to the problem, the firms were following an investment policy of rationalization. Emphasis was being placed on specialization to enable the industry to remain competitive. The industry has suffered from lack of a domestic market and consequent reliance on export sales, gradual depletion of easily accessible domestic ores, and need to import all coke and high-grade ore requirements. However, it has enjoyed the advantages of being located in the center of the ECSC, possessing relatively modern and efficient plants, operating a worldwide sales organization, holding a faithful clientele, and employing an unusually stable and experienced work force. The wage level in the Luxembourg steel industry is the highest in the ECSC.

MINERAL FUELS

Except for moderate quantities of hydropower, all energy consumed in Luxembourg is derived from imported mineral fuels. As in prior

Digitized by Google

years, about 70 percent of 1963 coal requirements were supplied by West Germany, the balance largely by Belgium and France. More than 85 percent of the coke, which has constituted the major item of mineral fuel imports, was supplied by West Germany, the balance originating in Netherlands and Belgium. At least some of the coke from Belgium was processed from U.S. coal shipped to that country under contracts with the Luxembourg steel firms of Hadir and Rodange. Imports of coal briquets and lignite showed moderate increases. Almost all the lignite is for household use. Imports of petroleum products continued to increase rapidly. As a result of the Vianden hydroplant going on stream in late 1962, hydropower output increased markedly from 110 million kilowatt-hours in 1962 to 486 million in 1963, raising the ratio of hydropower to total generation from 7 to more than 27 percent during this period. The Vianden

plant has a first stage capacity of 320,000 kilowatts (4 turbines), eventually to be increased to 640,000 kilowatts. Available statistics also show that imports of electric power increased from 242 million kilowatt-hours in 1962 to 970 million in 1963, while exports rose from 88 million to 492 million kilowatt-hours during the same period. Imports in 1963 were roughly two-thirds from West Germany and one-third from Belgium; about 90 percent of the electric power exports went to West Germany.

The Mineral Industry of the Netherlands

By Walter C. Woodmansee[1]

THE NETHERLANDS output of minerals and mineral products advanced considerably during 1963. As in previous years, metals and mineral raw materials (except natural gas and salt) were at least in part derived from foreign sources of supply; for several commodities, the country was entirely dependent upon imports for raw materials.

The year was one of continuing expansion in the principal mineral industries—petroleum, natural gas, and iron and steel. Construction continued on port and distribution facilities for crude oil and petroleum products. Natural gas exploration was extensive, and development of new fields proceeded through the year. The iron and steel industry was in the midst of an expansion program that would increase crude steel capacity by 30 percent during 1964.

Continuing seismic and drilling activity for natural gas was the most publicized news of the Netherlands minerals industry during 1963. Many companies joined the search, which has extended from the northern provinces to the offshore islands, estuaries, continental shelf, and the North Sea. Important discoveries were reported, and by yearend, reserves appeared to rank with the largest known fields in the world. As exploration continued, the government, in conjunction with private industry, proceeded with construction of pipelines and storage facilities for distribution of natural gas throughout the country.

The Netherlands led Western Europe in petroleum-products trade during the year. Four oil refineries in the Rotterdam area, having total capacity of more than 500,000 barrels per day, represented the largest concentration of this type in Western Europe. The country ranked fourth in Western Europe in crude oil output and fifth in refinery capacity and output of refined products. The Royal Dutch Shell refinery at Pernis, near Rotterdam, was the largest in Western Europe.

Large bunkers for residual and distillate fuel oils were maintained at Netherlands ports. Nearly half the cargo traffic of Rotterdam was in petroleum and petroleum products. Construction at Europoort continued as piers, storage tanks, pipelines, and a pumping station were completed. This development was only the beginning of a vast

[1] Foreign mineral specialist, Division of International Activities.

Digitized by Google

program in which Rotterdam and the national government planned to spend f700–800 million [2] and private industry f1.8 billion.

GOVERNMENT POLICIES AND PROGRAMS

The government has encouraged both domestic and foreign private investment in mineral industries of the country. Prospecting and exploration have been permitted throughout most of the country with permission of landowners, except in certain coal-mining districts. The government through the Council of State, however, owns all subsurface natural resources and has reserved the right to grant or withhold mining concessions after discovery.

The government has participated in the coal, oil, and natural gas industries through several organizations. State Mines (Staatsmijnen), under the jurisdiction of the Ministry of Economic Affairs, continued to operate the largest coal mines, coke plants, coal- and oil-based chemical plants, fertilizer works, and other industrial and commerical enterprises. Private coal-mining operations have been limited to concession areas established many years ago. However, State Mines and the private companies have worked in close cooperation. Both have been subject to regulations imposed by the Ministry and the High Authority of the European Coal and Steel Community.

NAM (N.V. Nederlandsche Aardolie Mij.—Netherlands Oil Co.), a joint subsidiary of Shell and Esso, held large oil and gas concessions including the highly productive Groningen Province, and had exclusive rights to crude oil and natural gas production in the country. Petroleum distribution companies maintain mandatory stock levels equal to 20 percent of previous year sales. More recently, the government has participated in the Netherlands Gas Union (N.V. Nederlandsche Gasunie), which coordinated natural gas production, distribution, and sales.

No definite policy was established regarding exploration for oil and gas on the continental shelf. NAM has explored offshore with consent of the Ministry of Economic Affairs. Within the 3-mile limit, exploration has been permitted as on land. However, the government did not ratify the policy adopted by the 1958 Geneva Convention on the Continental Shelf, which established the 3-mile zone of territorial waters. An announcement late in the year indicated a new mining law was being drafted.

SOURCE MATERIAL

The Statistical Yearbook of the Netherlands (Jaarcijfers voor Nederland), published by the Central Bureau of Statistics (Centraal Bureau voor de Statistiek), was the source of most production statistics through 1962. The Monthly Statistics of Imports, Exports and Transit, by Commodity (Maandstatistiek van de In- Uit- and Doorvoer per Goenderensoort) of that agency was the basis for import and export tables. Other sources of information were the publications of the European Economic Community, particularly for iron and steel, coal, and petroleum. Mineral and metal published periodicals and

[2] The monetary unit of the Netherlands is the guilder (f). One guilder is equal to US$0.276.

Digitized by Google

U.S. Embassy dispatches provided much of the information on recent developments in minerals.

PRODUCTION

Output of most metals and minerals was improved during the year of review. Although exact values were not available, the petroleum, coal, and iron and steel industries were the principal sources of income within the minerals sector of the Netherlands economy. Production of crude oil, most petroleum refinery products, and natural gas was higher than in 1962, and coal and manufactured gas output showed little change. Output of nearly all phases of the iron and steel industry from the sintering of imported ores to rolled steel products increased during 1963. The diamond industry, highly developed and employing a large labor force, has not publicized its processing activities and the extent of its output.

Production of lead and tin increased slightly during the year, but output of zinc has been gradually declining since 1960, owing to a continuing shortage of ore supply. Copper output, entirely secondary, has remained fairly uniform for several years.

Among the nonmetals, output of cement, salt, and sulfur was higher than in 1962. The fertilizer industry was involved in company mergers and plant expansions, and fertilizer output was expected to show continued improvement, although there was little change during the year.

Refinery do	10,860	15,749	21,383	22,691	(6)

[1] In addition to commodities listed, the Netherlands also produced the following, but quantity of output is not reported: Unconsolidated construction materials, building stone, byproduct and secondary precious and nonferrous metals, and carbon black.
[2] Secondary production, including alloys, in foundries.
[3] Estimate.
[4] Includes liquid steel for castings.
[5] Production for year ended June 30 of the year stated.
[6] Data not available.

TRADE

Both exports and imports of most mineral commodities were notably higher in 1963. Petroleum trade, by far the most important element of mineral trade in both tonnage and value, attained a record high as the industry prospered and expanded. Exports of rolled steel increased 47 percent while imports also advanced to new highs.

Total value of metal and mineral imports exceeded exports by f1.6 billion during the year. Imports were valued at f4.8 billion, while exports totaled f3.2 billion. These values, however, do not include

Digitized by Google

crude oil and petroleum product receipts by and deliveries from storage in bonded warehouses.

The metal and mineral exports were distributed, in terms of value, as follows: Petroleum products, chiefly gasoline and the fuel oils, 45 percent; metals, mainly iron and steel, 28 percent; coal and coal products, 16 percent; and nonmetals, chiefly fertilizers and diamonds, 11 percent. Corresponding percentages for imports were: Petroleum, predominantly crude oil, 41 percent; metals, largely iron and steel, 35 percent; coal and coal products, 14 percent; and nonmetals, 10 percent.

TABLE 2.—Exports of metals and minerals

COMMODITY REVIEW

METALS

Primary base metal production in the Netherlands is limited to two major companies. Crude metals produced include lead, zinc, tin, and a variety of other nonferrous metals in small quantities. There is no primary copper production; the entire output is secondary copper, produced largely by one company. Several secondary nonferrous metals and alloys also are produced in small quantities at numerous foundries, many of which also have milling facilities. Aluminum output also has been entirely by secondary smelters, but arrangements have been completed for an electrolytic reduction plant in the country.

The iron and steel industry, most important of the metals in both tonnage and value of output, is comprised essentially of one main company, Hoogovens, which operates in close association with the Government, and numerous foundries and mills.

Aluminum and Bauxite.—During 1963 the Netherlands aluminum output remained limited to a few thousand tons of secondary ingot by several foundries and nonferrous scrap processors. Imports of ingot and semimanufactured aluminum products, the principal supplies, were notably higher than in the previous year.

TABLE 4.—Principal producers of nonferrous metals and alloys

Company	Location		Facilities	Remarks
	City	Province		
N.V. Hollandsche Metallurgische Industrie Billiton.	Arnhem	Gelderland	Ore roasting and leaching plants, 4 large reverberatory furnaces, rotary furnaces; recovery from flue gases by electric filters. Metallic ores and metals processed include tin, lead, antimony, tungsten, vanadium, bismuth, molybdenum, chromite, silver, cadmium, about 80 alloys of these metals. Research and ore-dressing laboratory; pilot-plant facilities.	Subsidiary of N.V. Billiton Maatschappij, which has large foreign bauxite and tin holdings. Capacity: 40,000 tons various metal products annually.
N.V. Kempensche Zinkmaatschappij.	Budel	Noordbrabant	23 zinc furnaces; concentrates, scrap and ashes are treated; rolling mill.	Netherlands only zinc smelter; capacity 40,000 tons slab zinc, 10,000 tons zinc sheet, 100 tons cadmium.
Lips, N.V. Metaalbedrijf.	Drunen Brunsum	Noordbrabant Limburg	Refinery, foundry, rolling and extrusion mills; 5 rotary furnaces, 2 electric furnaces, 1 special reverberatory furnace, rolling mills with copper extrusion press; aluminum continuous casting unit and extrusion press, research and development laboratories.	Products include secondary copper, lead and zinc alloy ingots and mill products; nickel, brass and other alloy strip and bars; secondary aluminum ingot. Copper capacity 14,400 tons; aluminum capacity 3,600 tons. Total output: about 25,000 tons annually.

TABLE 5.—Selected ferrous and nonferrous rolling and extrusion mills, 1962[1]

Company	Location		Plant, products, remarks
	City	Province	
Hollandsche Draad-en Kabelfabriek, N.V.	Amsterdam	Noordholland	Steel and copper wire drawing and cable works at Amsterdam and Delft; nonferrous wire plant and cable works at other locations.
	Delft	Zuidholland	
	Enkhuisen	Nordholland	
	Delfzijl	Groningen	
Bleriksche Buizenfabriek, N.V.	Blerik	Limburg	Welded steel pipe and tube works.
Industrie v/h Van Lohuizen en Company, N.V.	Vasen	Gelderland	Rolling mill and foundry for iron, aluminum and copper; also tin, lead foil, solder. Aluminum powder metallurgical plant. Subsidiary plant at Nunspeet (Gelderland).
Rouppe van der Voort's Industrie en Metaalmaatschappij, N.V.	Hertogenbosch	Noordbrabant	Wire mill, foundry; lead and tin. Produces solders, tin-lined tubes, other manufactured articles.
Nederlandsche Aluminum Maatschappij, N.V.	Utrecht	Utrecht	Rolling and extrusion mills, foundry; aluminum sheet, foil, strip, other semifabricated; largest aluminum mills in country. Aluminium, Ltd., Canada, holds 40 percent interest.
Zuid-Hollandsche Pletterijen.	Delft	Zuidholland	Formerly D.A. Hamburg, N.V. Rolling mill and foundry; lead, zinc and copper. Variety of lead shapes, zinc ingots, copper tubes, solder. Capacity: 15,000 tons lead product, 5,000 tons remelted zinc.
Koperpletterijen en Metaalhandel.	Apeldoorn	Gelderland	Rolling mill and foundry; copper and tin. Solder, semifabricated products.
Koninklijke Nederlandsche Lood en Zinkpletterijen, N.V.	Utrecht	Utrecht	Rolling and extrusion mills; foundry. Various semifabricated products of lead and zinc; tin solder and alloys.
Fabrieken van Klinknagels en Schroefbouten, P. van Thiel en Zonen, N.V.	Beek en Donk	Noordbrabant	Iron, copper, bronze and aluminum wire mill.
Philips Draadtrekkerij	Geldrop	Noordbrabant	Copper, tungsten and molybdenum wire mill; more than 20 metal and alloy wires for electronic and electrical products of parent company, N.V. Philips Gloeilampenfabrieken.
Meta-Gelria, N.V.	Arnhem	Gelderland	Aluminum, brass and bronze wire mill.
Aluminum Extruders Holland, N.V.	Harderwijk	Gelderland	Extrusion plant completed by Aluminium Extruders International, Canadian firm, in 1960. Expansion agreement in 1962 with Reynolds Aluminum Co.

[1] In addition, there are 25 to 30 iron, steel, and nonferrous metal foundries and secondary metal producers in the country.

TABLE 6.—Principal iron and steel plants

Company	Location		Facilities	Remarks
	City	Province		
Koninklijke Nederlandsche Hoogovens en Staalfabrieken, N.V.	Ijmuiden	Ijmuiden	Seven coke-oven batteries, byproduct recovery plant; 3 sinter plants; three 235-ton and two 500-ton blast furnaces; pig iron desiliconization plant; six 200-ton open hearth furnaces; three100-ton LD stee converters and 2 oxygen-generating plants; slabbing, blooming, and plate mill; cast iron pipe foundry.	Ownership: Netherlands Government about 27 percent; Amsterdam about 10 percent; remainder private. Additional rolling capacity under construction. Capacity: 2.5 million tons ingots in 1964.
Breedband, N.V.	do	do	Rolling mills for Hoogovens steel; blooming mill; hot and cold strip mills; cold reduction temper mill; tandem mill; batch annealing plant; 8 automatic hot-dip tinning lines; 2 electrolytic tinning lines.	Ownership: Netherlands Government 92 percent; Hoogovens, 8 percent. Tinplate capacity 250,000 tons 1962; 400,000 tons 1965.
Koninklijke Demka Staalfabrieken, N.V.	Utrecht	Utrecht	Plant No. 1: two 60-ton open hearth furnaces; 5 electric furnaces: blooming mill; high-speed wire and rod mill; ferroalloys and special steels. Plant No. 2: Foundry, forge, cold drawing mill.	Hoogovens owns 51 percent of capital stock. Capacity 200,000 tons forging-grade steel; 150,000 tons rolled products.
	Blerik	Limburg	Wire-drawing and wire products plant.	
Nederlandsche Kabelfabrieken, N.V.	Ablasserdam	Zuidholland.	Three 35-ton open hearth furnaces; 3 electric furnaces; continuous bloom, billet, rod, and strip mill; cold-strip mill; plate mill; galvanizing plant.	Merged with Hollandsche Draad-en Kabelfabriek, N.V., in 1958. Largest producer of wire and cable. Capacity 200,000 tons.
	Delft	do	Steel cable works.	

Considerable progress was made toward completing the first alumina and aluminum reduction plants. Alusuisse, large aluminum producer in Switzerland, planned an extensive aluminum complex at Botlek (Zuidholland), along the New Waterway (Nieuwe Waterweg) to Rotterdam. Alusuisse formed a subsidiary, Aluchemie, N.V., headquartered at Rotterdam, which commenced construction of an f80-million carbon electrode plant and continued planning for a 200,000-ton alumina plant and a 100,000-ton rolling mill. Hoogovens, the Dutch steel concern, and Billiton, the Dutch tin producer and also a major producer of bauxite, are associated with Alusuisse in the rolling-mill venture. Reportedly, f800 million will be expended on this project over a period of 10 years. Alumina produced is to be shipped to Alusuisse electrolytic plants in Norway, West Germany, Switzerland, and Italy for conversion to aluminum. Alusuisse apparently selected the Rotterdam area plant site because of its central location in relation to the European aluminum reduction facilities, and also because of the excellent marine and inland waterway transportation from Rotterdam.

Hoogovens, Billiton, and Alusuisse agreed to proceed jointly with construction of the Netherlands first electrolytic aluminum reduction plant near Delfzijl (Groningen) on the north coast. Initial plant capacity, 30,000 tons annually is expected to be doubled at a later

758-002—65——42

Digitized by Google

date. Total investment was estimated at approximately f200 million. Share capital was distributed as follows: Hoogovens 50 percent, Alusuisse 33⅓ percent, and Billiton 16⅔ percent. The Delfzijl site was selected because of its proximity to the large natural gas resources of Groningen Province, which will provide fuel for electric power generation.

Greece and Surinam are expected to be the principal sources of bauxite for the Botlek alumina plant. Billiton, one of the largest nonintegrated bauxite mining companies in the world, has completed arrangements with Suralco (Surinam Aluminum Co., a subsidiary of Aluminum Company of America) for bauxite processing in Surinam. Bauxite mined by Billiton in this country is to be processed in a new Suralco alumina plant, the alumina product to be exported to the Netherlands and the United States by N. V. Billiton Mij. Suriname, the Surinam subsidiary of Billiton. Suralco agreed to produce a maximum of 130,000 tons alumina per year from the Billiton bauxite. This arrangement depended on Dutch natural gas prices in Groningen Province and the decision to construct the new aluminum reduction plant at Delfzijl. The Dutch Government reserved a certain quantity of natural gas on special terms for new industries, including the Delfzijl aluminum venture.

During 1963 officials of Kaiser Aluminum Co. (United States) and Pechiney (France), continued investigation of the possibilities for another reduction plant in the Netherlands, but at year end no definite decision had been reached. A site near Amsterdam was considered favorable.

Copper.—Production of unwrought copper remained limited to several thousand tons annually of secondary ingot, which provided for only a small part of annual demand of industry. The main supplies continued to be from imported semimanufactures, receipts from which during 1963 were approximately the same as in 1962. Imports of unwrought copper increased slightly in 1963, and exports of scrap to West Germany and Belgium continued high.

Electrical product manufacturers, shipbuilders, and the automotive industry have been the principal users of copper in recent years. Demand continued high during 1963, as consumption ranged from 40,000 to 50,000 tons per year.

A new institution, The Netherlands Copper Institute (Nederlands Koper-institut), was founded at The Hague to promote production and use of copper and copper alloys throughout industry. This institute was to provide information and technical advice on these subjects.

Iron and Steel.—Output of crude, semifinished, and finished steel increased further during 1963, while the ambitious modernization and expansion programs were under way. However, only part of the steel requirements were met by domestic production, and imports of iron ore, pig iron, scrap, and all forms of steel were higher during the year.

Source: Statistical Office of the European Communities, Iron and Steel, 1964, No. 3.

Output of pig iron and crude steel was about 10 percent higher than in 1962, and output of rolled and finished steel increased at a slightly greater rate. Hoogovens (Koninklijke Nederlandsche Hoogovens en Staalfabrieken, N.V.—Royal Netherlands Blast Furnaces and Steelworks), the dominant iron and steel company in the country, accounted for all of the pig iron, 87 percent of the crude steel, and (largely

Digitized by Google

through its affiliate, Breedband, N.V.) about 80 percent of the steel products.

During 1954–62 more than f1 billion was invested in industry improvement programs. All four steelmaking companies continued new construction and plant renovation during 1963. Overall planned capacity for the end of 1964 was 2.15 million tons pig iron, 3 million tons ingot steel, 2.2 million tons rolled steel, and 250,000 tons castings. Expansion to capacity of 5 to 7 million tons ingot steel has been planned over the next several years.

Hoogovens has undergone a marked change from open hearth to oxygen converter steel since 1962. In 1963 about 70 percent of the company crude-steel output of more than 2 million tons was oxygen steel, and future steelmaking will include a higher proportion of oxygen steel. Hoogovens alone planned for crude-steel capacity of 3.4 million tons and production of 3 million tons by 1965.

Source: Royal Netherlands Blast Furnaces and Steelworks, Ijmuiden; Annual Report, 1963.

During the year Hoogovens commenced construction of a new blast furnace, which would be fired during 1964, at Ijmuiden, the center of company steelmaking activities on the North Sea coast. A second slabbing and blooming mill went into operation in late 1963; raising slab and bloom capacity 1.5 millions tons to a total of 3.4 million tons. Construction on a second rolling mill continued during the year and is scheduled for 1964 completion. This rolling mill for merchant bars and rods will further diversify Hoogovens range of steel products, which formerly was limited to flat-rolled products.

Demka (Koninklijke Demka Staalfabrieken, N.V.—Royal Demka Steelworks), the Netherlands producer of special steels and ferroalloys, experienced some difficulty in getting a new rod and wire mill into production during the year, because of both technical difficulties and a shortage of trained and experienced personnel. The company also has initiated an improvement plan for its blooming and other rolling mills. An agreement continued with Carpenter Steel Co. (Reading Pa.), which provided technical and commercial assistance to Demka on spe-

Digitized by Google

cial steelmaking. As result, Demka introduced new types of stainless and tool steels during 1963.

NKF (Nederlandsche Kabelfabrieken, N.V.—Netherlands Cable Works) reportedly invested f80 million in expansion of steel capacity during the year, including oxygen steel, and in a new rolling mill at Ablasserdam (Zuidholland). The planned production target was 600,000 tons ingot and 500,000 tons finished steel by 1964. During 1963 the company issued new shares to increase capitalization for financing this continuing project, which also includes a new blast furnace and sintering plant. The mill is to be specially equipped to handle 5- to 8-ton ingots.

The General Scandinavian Import Steel Co. (Algemene Scandinavische Import Staal Mij., N.V.), Zwijndrecht (Zuidholland), made plans to establish an industry for the rolling and drawing of stainless steel in the vicinity of Terneuzen (Zeeland). The crude steel would be imported from Sweden. Many aspects regarding this project, however, were uncertain at yearend.

No decision was made concerning a new steel complex in the Rotterdam Europoort development project during the year. The proposed site on Rozenburg Island along the New Waterway had been held for several years, pending a decision by Rotterdam officials, the Government, and the iron and steel industry on feasibility of such a project. This land was sought by other industry during the year, and late in the year it appeared that interests other than the steel industry would proceed with Europoort development and that iron and steel development would be considered further in 1964.

Lead and Zinc.—Billiton (N.V. Hollandsche Metallurgische Industrie Billiton), the Netherlands only primary lead producer, increased production of pig lead nearly to the 1959–60 level. The main raw material supplies were domestic scrap and imported bullion and scrap. Imports of pig lead were lowered considerably during the year, as compared with 1962.

Output of slab zinc at the Budel (Noordbrabant) smelter of N.V. Kempensche Zink Mij., which accounted for the entire domestic production of slab zinc, dropped slightly during the year, owing to a continuing shortage of ore supply. Ore imports were higher than in 1962 but remained well below tonnages received in previous years. Zinc consumption was at an approximate annual rate of 30,000 tons during the year.

Nickel.—Small secondary production of nickel and nickel alloy ingots for ferrous and nonferrous uses continued at the Amsterdam plant of Nederlandsche Nikkel Mij., N.V. This plant has capacity for 2,000 tons of these ingots annually.

Precious Metals.—Small quantities of the precious metals have been derived as byproducts at the Arnhem (Gelderland) and Budel (Noordbrabant) nonferrous smelters, but essentially all of the Netherlands supply of gold, silver and platinum continued to come from imports of these metals in all forms. There was no significant change in trade patterns for silver and platinum during 1963; sources and quantities of gold supply are not known.

Tantalum and Columbium.—Kawecki Chemical Co. (New York) joined with Billiton on a 50–50 basis in a new company, KBM (N.V.

Digitized by Google

Kawecki-Billiton Metallindustrie), having a plant at Arnhem (Gelderland) that will produce columbium-tantalum sheet and foil, tantalum anodes, high-purity indium, and other rare metals in a variety of industrial forms.

Tin.—The Billiton Arnhem smelter received the first shipment of Indonesian tin concentrate since 1958. Domestic output has slowly recovered but has not reached pre-1960 production rates. During the years of loss of Indonesian concentrate, a shortage of world supply, and rising tin prices, greater quantities of the metal were imported from U.S.S.R. and mainland China. With resumption of raw materials supply from Indonesia, Billiton planned to process 12,000 tons of concentrate annually.

Early in 1963, Billiton concluded an agreement with the French CFE (Compagnie Française de L'Etain), under which Billiton acquired half of the share capital of CFE. These two companies have therefore become closely associated in the tin technical and commercial fields.

Titanium.—Billiton, Royal Salt Ketjen, and Cyprus Mines (United States) have joined in N.V. Titaandioxydefabriek (Titanium Dioxide Works) in the Botlek (Zuidholland) area. This company will produce 10,000 tons TiO_2 annually when full production is reached. During 1963, output was gradually increased after initial chemical difficulties were overcome. The highly competitive world market for titanium white, falling prices, and increased construction and operational costs introduced problems which were alleviated as productivity increased.

NONMETALS

Cement.—Domestic output of cement, which surpassed 2 million tons in 1962, continued an upward trend during 1963. Imports of large quantities also continued from Belgium and West Germany. The Netherlands cement industry produced about 60 percent of estimated consumption of 3.5 million tons during the year. An increased consumptive rate is anticipated, owing not only to high demand throughout industry but also to the Delta Plan, under which the estuaries of the Zeeland coast are to be closed off, and to the continuing reclamation projects in the Ijsselmeer.

Cemij (Cementfabriek Ijmuiden), a Hoogovens-ENCI (N.V. Eerste Nederlandsche Cementindustrie—First Netherlands Cement Industry) partnership, produced 812,000 tons of cement, an 8-percent increase over that of 1962. Construction began on a new plant, sponsored by the same partnership, on Rozenburg Island. Cement production from this plant was expected during 1965.

ENCI continued production at its Maastricht (Limburg) plants. Blast-furnace slag as well as imported limestone have been used at both Ijmuiden and Maastricht, the former utilizing slag from the Hoogovens steelworks and the latter from Liège, Belgium.

Diamond.—Imports of crude, worked, and powdered diamond increased from 1962. Total value of imports for gem stones and abrasives was nearly f90 million. Six major companies in Amsterdam and 40 others in the country were involved in trading, sorting, grading,

Digitized by Google

cutting, and polishing diamonds. The processed products have largely entered the export market, valued at nearly f100 million in 1963.

Fertilizers.—Output of phosphatic fertilizers continued to decline during the year, whereas output of nitrogenous types increased slightly. Production of potassic varieties remained small. With an increase in overall fertilizer consumption of 2 to 3 percent, imports of natural nitrates, phosphate rock, basic slag, and all manufactured fertilizers were higher in 1963.

Three large companies, the Royal Dutch/Shell, Hoogovens, and KNZ (the latter N.V. Koninklijke Nederlandsche Zoutindustrie—Royal Netherlands Salt Industry), have cooperated closely, through subsidiaries, for improved efficiency in production and sales of fertilizers. They have formed a new holding company, VKF (Verenigde Kunstmestfabrieken Mekog-Albatros, N.V.—United Fertilizer Works Mekog-Albatros) with ownership as follows: Royal Dutch/Shell, 40 percent, and Hoogovens, 20 percent, through their subsidiary Mekog (N.V. Mij. tot Exploitatie van Kooksovengasse—Company for Exploitation of Coke Oven Gas), and KNZ, 40 percent, through its subsidiary Albatros Superfosfaatfabrieken, N.V.—Albatros Superphosphate Works). VKF has coordinated the continuing expansion of operations of these companies in the fertilizer field. Older plants have been improved and enlarged, and several large new works have been built or are planned.

State Mines, the government coal-mining agency, which also has entered the chemical and fertilizer fields, produced 948,000 tons of nitrogenous fertilizers during the year, a significant increase over 1962. Another large producer of standard and double superphosphate has been ENCK (Eerste Nederlandsche Cooperatieve Kunstmestfabriek—First Netherlands Cooperative Fertilizer Works), which has a 225,000-ton works at Vlaardingen (Zuidholland) along the New Waterway to Rotterdam.

Salt.—Production of salt has shown a steady growth, which was 13 percent in 1962 and 18 percent in 1963. Imports of salt more than doubled during the year but still remained small relative to production and exports. About 60 percent of the annual salt supply has been exported in recent years; 40 percent, or about 600,000 tons, has been absorbed in domestic consumption.

The main deposits and installations at Hengel (Overijssel), near the West German border, have capacity for 800,000 tons of salt annually. Reserves here were reported to be 500 million tons in the Triassic Bund sandstone. Similar but smaller scale operations continued on a salt dome at Winschoten (Groningen) in the northeast and at Spijkenisse (Zuidholland), near Rotterdam. All are owned and operated by the Royal Netherlands Salt Industry (Koninkijke Nederlandsche Zoutindustrie). Brine salt from depths of 1,000 to 1,200 feet is precipitated by evaporation and is purified by electrolysis at Hengelo. Winschoten brine has been fed by pipeline to the company 350,000-ton plant at Delfzijl (Groningen), where salt was processed principally for the export market.

KNZ has diversified its activities in recent years. The company, through subsidiaries, has participated in several fertilizer and chemical industry ventures, both domestic and foreign.

Digitized by Google

Sand and Gravel.—A large quarrying industry for unconsolidated construction materials was active during the year but production is not known. Deliveries to the consuming sectors reportedly totaled 46.7 million tons in 1961 and 45.3 million tons in 1962. Large quantities of construction sand and crushed rock have been involved in trade.

Sulfur.—The Netherlands sulfur supply continued to be provided largely by imports, which have gradually increased in recent years. Limited, uniform domestic output of liquid sulfur accounted for about 20 percent of consumption during the year. The use of pyrite as a source of sulfur for sulfuric acid has decreased as the use of native and recovered sulfur has increased. The principal consumer of pyrite was Albacid, a subsidiary of the Albatros superphosphate works.

Sulexco, an American export organization, was constructing the first European installation for transhipping liquid sulfur in the Botlek (Zuidholland) industrial area. Plant throughput capacity was reported to be 200,000 tons per year; construction costs were from f7 to f8 million. Facilities for loading and transhipping solid sulfur also were to be built. The operating company was reported to be the Netherlands Sulfur Storage Business (Nederlandsche Swavel Opslagbedrijf).

Liquid and solid sulfur also are to be recovered as byproducts of Europoort oil refining. About 30 tons per day were anticipated.

MINERAL FUELS

Coal.—Output of Netherlands coal mines was approximately the same as in 1962. There was a substantial gain in demand for coal, necessitating imports of anthracite and bituminous coals more than 1 million tons higher than in 1962. Imports were the highest since World War II. The United States provided 3.3 million tons during the year, approximately 50 percent above the previous year and the highest since 1958.

A large part of the coal output of the Netherlands was good-quality coking coal. About 40 percent was anthracite and semianthracite; 50 percent was medium-volatile bituminous; and 10 percent was low-volatile bituminous.

The Government-owned State Mines (Staatsmijnen) continued to operate 4 of 12 producing mines and was responsible for about 60 percent of the 1963 coal and coke production. State Mines profits fell during 1962–63 owing to a labor shortage and lower productivity.

The company has produced coal-based chemical products at Beek (Limburg) in the coal-mining region for many years and, more recently, has entered the field of petrochemicals with a new plant at Rotterdam, using oil refinery byproducts. State Mines also has entered the fertilizer field, making ammonia for nitrogenous fertilizers from enormous company supplies of coke-oven gas. A synthetic hydrogen plant and a methane-cracking plant also have provided hydrogen for ammonia production.

The four State Mines coal mines remaining active in 1963 and their approximate optimum annual production were the Emma, 2.5 million tons; Maurits, 2.5 million tons; Hendrik, 1.5 million tons; and Wilhelmina, 1 million tons. The company had developed another mine, the Beatrix, during 1954–62. This mine, however, was closed by the

Ministry of Economic Affairs, principally because of the growing importance of the natural gas fuels in Groningen Province. Other company operations during the year included two coking plants, briquet plants, several chemical works, gas distribution, power stations, research, a railroad system, shipping and port facilities, and sales offices.

Seventy to eighty percent of State Mines coal output was mechanized in 1963; only steeply inclined seams were mined by hand longwall methods. Hydraulic roof-support props have been gradually replacing existing friction props.

Source: Annual Reports, Staatsmijnen in Limburg, 1962 and 1963.

Coal resources, mostly in Limburg Province, were reported to total 4.6 billion tons, of which 1.7 billion tons were reserves workable under 1963 economic conditions. The gross resources were distributed, by quality, as follows: Bituminous 64 percent, semibituminous 20 percent, and anthracite-semianthracite 7 percent.

Petroleum.—*Crude Oil.*—Domestic output of crude oil continued to gradually expand, although still providing only a small part of annual requirements. Imports, including bunkering and bonded warehouses, increased nearly 10 percent from 1962 while crude oil from bonded storage was shipped to West Germany in larger quantities.

Production remained under the exclusive control of NAM (N.V. Nederlandsche Aardolie Mij.—Netherlands Petroleum Co.), which was formed by Shell Netherlands and Esso Netherlands in 1947. Numerous companies continued exploration, encouraged more by natural gas prospects but still hopeful of locating new oil fields. During 1962 there were 412 producing oil wells in 13 productive fields of the Northeast Basin, near the West German border, and in the Western Basin. Total oil reserves reported during the year were 250 million barrels.

Large companies and small independents were involved in expansion of storage, refining, distribution, and marketing facilities. Storage capacity in 1961 was estimated to be 55 million barrels at ports, refineries, storage depots, inland distribution centers, oilfields, and pumping stations. A further 4.6 million barrels of tankage capacity was either planned during 1962 or construction was underway. Pipelines consisted of relatively short lines from oilfields and from Europoort to the refineries. As new storage facilities were built at Europoort, new lines were extended to the refineries.

Refinery Products.—Production of most petroleum refinery products was greater than in 1962; only for jet fuels and distillate fuel oils was output known to be less. Imports of most products also were higher, especially of the fuel oils. Exports also increased during the year, as the Netherlands remained a net exporter of gasoline, fuel oils, lubricants, liquefied petroleum gas, and other products through bunkering and bonded warehouse sales.

Three operational refineries in the Rotterdam area have been actively engaged in expansion of capacity, storage, or distribution facilities. A fourth, a 30,000-barrel per-day plant under construction for Gulf Oil Corp. at Europoort, neared completion during 1963. Late in the year, Gulf announced plans to double the plant capacity. The Shell refinery at Pernis, largest in western Europe, had about 60 percent of total refinery capacity late in 1963, including the new Gulf

Digitized by Google

TABLE 11.—Activities of major oil and gas companies in 1962–63

Company	Affiliation	Recent developments
BPHM (Benzine en Petroleum Handel Mij., N.V.)	British Petroleum Co., Ltd.	Exploration team on Schiermonnikoog Island. Started drilling offshore islands and Waddenzee. Expanded storage capacity at Amsterdam.
Caltex (Caltex Petroleum Mij., N.V.)	California Oil Co. and Texas Oil Co.	Continued drilling in Zeeland and Brabant provinces, and offshore; subsidiary Amoseas discovered gas, depth 6,200 feet on Ameland Island. Associated with Gulf and Mobil in North Sea exploration; further seismic activity in shallow sea between mainland and offshore islands. Opened new unloading and storage facilities at Europoort. Expansion of refinery at Pernis completed to 80,000 barrels per day. Two gas storage tanks constructed 1962; capacity, 1.8 million cubic feet each; 12 more planned. Participated with Esso in pipeline from storage to Pernis and Botlek and on to the Rhine.
Esso (Esso Nederlandsche, N.V.)	Standard Oil Co. of New Jersey.	Exploration activities through NAM. Also holds 25-percent interest in N.V. Nederlandsche Gasunie, new government-controlled company for natural gas distribution and marketing. Storage capacity at Botlek (Europoort) enlarged. Continued production at Botlek refinery, capacity 100,000 barrels per day; construction of lube oil blending and packaging plant, capacity 750 barrels per day; aromatics plant; and new tankage of 550,000 barrels capacity. Continued construction of Esso-Rhine pipeline for direct oil shipments to Ruhr.
Gulf (Gulf Oil Nederlandsche, N.V.)	Gulf Oil Corp.	Associated with Mobil and Caltex in North Sea exploration. Continued construction of 30,000 barrels per day refinery at Europoort; builder is Kellogg International Corp., cost in excess of f100 million; will process a variety of crude oils.
NAM (N.V. Nederlandsche Aardolie Mij).	Shell Nederlandsche 50 percent; Standard Oil of New Jersey 50 percent (Esso).	Offshore exploration since 1956; completed 4 unsuccessful drill holes 1961–62 outside territorial waters; depths to 7,000 feet. Exploration continued 1963, including Ameland Island and Waddenzee, near mouth of Eems River. No exploration in 1963 beyond territorial waters. Made new gas discoveries, north coast Friesland Province and in Drenthe Province. Used helicopters in seismic surveys off Dutch coast; explosive charge fired from one helicopter; reflections measured in another. Controls largest concession areas, including Groningen Province. Oil and gas discoveries continued in numerous concessions; oil yield 38,000 barrels per day, 2 million tons per year, from 5 concessions. Numerous gas discoveries in northeast basin during 1962–63. Late in year, NAM and Brigitta, German subsidiary of Shell and Esso, announced gas reserve of 320 billion cubic feet in the Eems-Dollard estuary area between the 2 countries. Participated in N.V. Nederlandsche Gasunie, new gas distribution agency, on 50-50 basis with government, through Staatsmijnen (State Mines).
Royal Dutch—Shell Group (N.V. Koninklijke Nederlandsche Petroleum Mij. and N.V. Shell Nederlandsche).	With companies mainly in Netherlands, United States, France, Switzerland and United Kingdom.	Leading petroleum company in country; operates largest refinery and participates in exploration through NAM. Began work on largest crude oil storage tanks in the world at Europoort; tank diameter, 250 feet; height, 72 feet; capacity 630,000 barrels. Refinery at Pernis, 320,000 barrels per day, or 16 million tons annually. Storage at Amsterdam enlarged.

plant. Esso at Botlek had 19 percent; Caltex at Pernis had 15 percent; and Gulf at Europoort had 6 percent. A small asphalt refinery at Amsterdam, Smid en Hollander, continued production with a daily throughput of 4,300 barrels.

Natural Gas.—Data on the 1963 output of natural gas are not yet available. However, the total was probably greater than that in 1962 of approximately 41,000 million cubic feet of associated and nonassociated gas. Exploration was intensified on the mainland, offshore islands, territorial waters, and beyond the 3-mile limit in the North Sea. With approximately 90 percent of the country considered to be favorable for oil and gas, prospects for future discoveries remained

Digitized by Google

good. Gas reserves increased steadily during the year as discoveries or successful development wells were reported. Early in the year, reserve estimates were approximately 15 trillion cubic feet; at yearend a report by NAM, which has sole rights for natural gas production, showed reserves of about 40 trillion cubic feet.

[1] Estimate.

Source: Statistical Office of the European Communities, Coal and Other Energy Sources, 1964, No. 2.

Twenty gasfields were productive in 1962, 14 in the Northeast Basin and 6 in the Western Basin. The immense Slochteren field in Groningen Province was shut in during 1962 but was scheduled for limited production in 1963. Production from this province was about 22 billion cubic feet in 1962. The gas was reported to occur in anticlinal structures, some fault zones, and a salt dome (Delfzijl) in Upper Permian and Lower Cretaceous strata at maximum depths of 10,000 feet. Depths to productive zones are reportedly much shallower in the Western Basin.

Government authorities and private operating companies directed their efforts toward preparation of marketing facilities as well as exploration during the year. The first pipeline deliveries were made, and plans continued on a countrywide pipeline network linking the gasfields, refineries, and municipal and industrial consumers. Schedules called for gas supply in Groningen Province during 1963 and throughout the country by 1967. A 300-mile pipeline network under construction was scheduled for completion in 1964. A U.S. engineering firm reportedly supervised the pipeline construction, while Dutch firms built the measuring and other ancillary installations.

Natural gas exploitation is governed by NAM, 60 percent, and State Mines, 40 percent. A new organization, N.V. Nederlandsche Gasunie (Netherlands Gas Union), was formally established on a 50–50 basis between the government (State Mines, 40 percent, State, 10 percent) and NAM, to coordinate gas policy on purchasing, distribution, and marketing. Plans were made for investment of f700 million on distribution facilities during 1963–70.

Plans to market natural gas in foreign countries also were advanced. Long-term contracts were concluded with West German firms during the year, and discussions also were held with French interests. The possibility of a gas pipeline under the North Sea to the United King-

Digitized by Google

dom was proposed. Royal Dutch/Shell and Esso, partners in NAM, formed NAM Gas Export, to promote the sale of natural gas abroad, and International Gas Transport Co., to arrange for future transportation of natural gas by pipeline to Western Europe.

Natural gas prices, which are subject to approval of the Ministry of Economic Affairs, were of much concern to potential domestic and foreign consumers. Late in the year, the Gas Union announced domestic wholesale prices charged to local distributors would be 6 cents (Dutch) per cubic meter. Export prices were not given but were expected to be slightly lower. In establishing natural gas prices, the government attempted to keep rates in line with other energy fuels and to lessen any disruptive effects of a large cheap fuel supply on the energy market.

The Mineral Industry of Norway

By Charles D. Hoyt[1]

ALTHOUGH Norway has limited mineral resources, it possesses a large and valuable resource in hydroelectric energy potential, which in 1961 was officially estimated at 110 billion to 128 billion kilowatt-hours annually. In 1963, hydropower production totaled 40.2 billion kilowatt-hours. Intensive use of hydropower, combined with a high level of technology, has made Norway a significant world producer of metals and alloys, as indicated by the approximate percentages of world production in 1962: Aluminum, 4 percent; ferroalloys, 7 percent (estimated); nickel, 8 percent; electrolytic zinc, 4 percent (estimated); and cobalt, 4 percent.

The output of these commodities is almost completely based on the processing of imported raw materials. Domestic mineral production contributes partially to ferroalloy raw material supplies (iron ore and silica) and to electrolytic zinc production.

In addition to this group of import-based metal products, Norway has developed its own mineral resources, particularly since World War II, and the country in 1963 continued to contribute significant quantities to the world output of a number of commodities. On the basis of 1962 data, Norway provided the following shares of world output: Magnesium, 11.3 percent; ilmenite, 14.4 percent; columbium-tantalum, 8.0 percent; feldspar, 3.6 percent; pyrites, 3.9 percent; and talc and soapstone, 4.9 percent.

Large quantities of most of Norway's mineral products are exported and do not enter the domestic economy as consumption items. Therefore, in viewing Norway's role in the world mineral economy, it is meaningful to mention that the country ranked first in the world as an exporter of ferroalloys, magnesium, and feldspar; second in exports of aluminum, titania, nickel ingots, electrolytic zinc, columbium-tantalum, and talc and soapstone; third as a molybdenum exporter; and fourth in exports of pyrites, cobalt, and mica.

The processing and production of these items continued to be important to the economy of the country. It is estimated that the total contribution of mineral and metal output to the gross national product in 1963 was 4 to 4.5 percent. The industry employed 31,000 workers (3 percent of the country's 1 million wage earners), of whom 23,000 worked in metal production and 8,000 in mining and quarrying. Mineral commodities in 1963 remained the most important export group and represented an estimated 31 percent of total export value (18 per-

[1] Staff engineer, Office of Program Coordination.

Digitized by Google

cent of import values), a slight increase over that of 1962, in spite of lower average unit prices.

The role of U.S. capital in the mineral development and economy of Norway has been appreciable but by no means dominant. The most important U.S. ownership within the mineral and metal industry has been in ferroalloy and titania output. The U.S. firm Union Carbide operates one of Europe's largest ferroalloy plants, and another U.S. firm, National Lead, owns the Norwegian titania operations, which are among the largest in the world.

The outstanding development during 1963 was the entry of two major U.S. aluminum producers, Alcoa and Harvey, into the country's aluminum industry. Alcoa entered joint ownership with one of the existing major aluminum producers, which is expanding its plant capacity. Harvey joined with one of the major Norwegian chemical (and magnesium) producers, Norsk Hydro, in a joint venture to build a 60,000-ton-per-year aluminum plant in western Norway. Capital investment projections for these and other increases in the country's aluminum capacity during the next few years total nearly one-quarter of a billion dollars. This estimate includes all costs for building additional power facilities, which have been approved by the Norwegian Government. Scheduled completion date for these new plants is 1965–67.

Investment in the Norwegian aluminum industry by such important aluminum producers portends well for the future of Norway's aluminum industry, which has been expanding very rapidly in recent years. Since 1950 output has more than quadrupled, reaching 211,000 tons during 1963. Developments within the Common Market are of particular interest to Norway since the common market countries are in short supply of aluminum.

GOVERNMENT POLICIES AND PROGRAMS

During 1963 there were no actual changes in the Government's policies toward the mineral industry or its extensive ownership within it. However, there was a substantial reassessment of these investments following a series of political events which were interwoven with problems concerning Government mineral operations and related to the philosophy of Government ownership of mineral industries. The Norwegian Government retained outright ownership or control of the major portion of the iron ore output, iron and steel production, aluminum output and several other mineral commodities of lesser importance. The economic results of these various Government enterprises during 1963 were sharply different. The iron ore and aluminum industries continued to be operated at a considerable profit. Profits for 1963 from the State-owned aluminum complex were officially estimated at nearly $5 million.

In contrast, the Government-owned steel plant at Mo i Rana continued to operate at a considerable deficit; the loss for 1963 was about $4 million, according to a Government report released in April 1964. This same report stated that the net total operating loss from the start of operations in 1955 to June 30, 1963, was more than $11 million. It further projected losses for 1964 and 1965, to total another $8.4

Digitized by Google

million. The Government also proceeded with the building of a coke and ammonia plant to be used in conjunction with the steel plant. This coke complex, which reportedly is to begin operation in mid-1964, has been a considerable source of dissatisfaction within the Government and the country because the original cost estimates of $20 million have been exceeded by an estimated 75 percent and the expected startup date has been delayed a number of times.

A third problem area within the Government mineral operations resulted in the fall of the Labor Government in August 1963. In November 1962, a serious explosion which cost 21 miners' lives occurred at the State-owned coal-mining operations at Kings Bay on the arctic island of West Spitsbergen. The operation was shut down following this disaster, and a no-confidence vote over the Government's conduct and responsibility for these operations resulted in the fall of the Government. Within less than 1 month, the opposition coalition government that took over was forced to resign and the Labor party returned to power. Subsequently, the Kings Bay coal-mining operation was closed indefinitely and was being liquidated at yearend.

These events have caused the Norwegian Labor Government to be cautious in making further major industrial investments. For example, a careful study is now being made by the Government to determine what should be done about the operations and intended expansion of the Mo i Rana steel plant.

PRODUCTION

During the year the country's mineral industries registered a mixed pattern of production changes. The light metals industries all showed increases in output, as well as significant activity in planning for and building additional production capacity to be available within a few years. There were small production increases within the ferrous industries, but the economic results, particularly at the major iron and steel producer, continued to be disappointing and of concern to the Government, which owns the operation. One major metal processor (nickel) encountered unusual marketing difficulties early in 1963 and had to reduce both its output and its work force temporarily. However, market conditions improved considerably by yearend.

TRADE

With few exceptions, Norwegian mineral and metal-processing output is exported; hence, comments on production, as well as the production changes, reflect what happened to the export markets.

Preliminary pricing information for the first three-quarters of 1963 indicated that export sale prices for nearly all the traditional export mineral commodities decreased, except for zinc. Nevertheless, total

Digitized by Google

value of mineral exports for 1963 will probably remain the same or increase slightly owing to moderate increases in production and exports, principally in aluminum and magnesium and, to a lesser degree, ferroalloys. It is the considered opinion of some Government officials that lower world prices for many export commodities and services (that is, shipping) are not merely short-range phenomena, but long-range, economic facts of life. This condition has developed principally through new techniques of production and transport throughout the world, and to compete with these expected permanent lower export prices, Norway will have to make similar advances in technology.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Ingot, unalloyed and alloyed	146,295	171,690	United Kingdom 50,408; United States 49,867; West Germany 29,298.
Semimanufactures	5,665	5,907	Denmark 2,257; Sweden 1,407; Finland 677.
Cadmium, ingot	93	87	(1).
Cobalt, unwrought	636	645	(1).
Columbium-tantalum ore	195	268	(1).
Copper:			
Ore	10,606	11,385	West Germany 5,908; Sweden 5,477.
Matte	19,882	15,759	Sweden 10,442; West Germany 5,317.
Ingot:			
Unrefined and refined	19,057	17,957	West Germany 10,606; France 4,277; Switzerland 816.
Alloy (including all copper scrap).	3,407	2,811	West Germany 1,463; Sweden 772; Italy 436.
Semimanufactures	2,472	2,232	United States 682; Denmark 630; Netherlands 453.
Iron and steel:			
Iron ore	1,138	1,269	West Germany 810; United Kingdom 302; Poland 113.
Pig iron	119,850	135,119	United Kingdom 48,620; West Germany 31,255; Belgium-Luxembourg 10,718.
Ferroalloys:			
Ferromanganese	48,120	46,580	Belgium-Luxembourg 11,447; West Germany 9,470; Netherlands 6,526.
Ferrosilicon	161,930	135,909	United Kingdom 54,892; West Germany 41,872; Belgium-Luxembourg 14,076.
Ferrosilicomanganese	86,254	71,702	West Germany 23,234; United Kingdom 17,059; United States 9,025.
Ferrochrome	21,593	17,067	United Kingdom 4,359; United States 3,677; West Germany 2,659.
Ferrosilicochrome	3,209	2,673	United Kingdom 1,537; Sweden 446; West Germany 342.
Others	1,208	924	United Kingdom 463; West Germany 147.
Steel ingots and equivalent primary forms.	27,365	48,891	Netherlands 20,433; Denmark 11,808; Greece 5,999.
Semimanufactures	121,800	133,347	Sweden 33,727; U.S.S.R. 14,521; Denmark 14,453.
Lead:			
Ore	3,440	5,151	All to West Germany.
Ingot, unalloyed and alloyed	489	255	Sweden 122; Finland 34.
Scrap	2,394	2,407	Denmark 1,430; Italy 609; Sweden 287.
Semimanufactures	229	424	Sweden 341; Iceland 46.
Magnesium:			
Unwrought	12,352	14,759	(1).
Scrap and semimanufactures	220	152	Italy 92; West Germany 54.
Manganese ore	406	203	United Kingdom 203.
Molybdenum concentrate	400	488	(1).
Nickel:			
Ingot	29,676	27,680	United States 13,960; West Germany 5,091; Sweden 3,933.
Semimanufactures and scrap	1,000	860	Sweden 266; West Germany 187; Italy 112.
Platinum metal, troy ounces	10,706	15,786	United States 12,956; Netherlands 1,608; United Kingdom 1,157.

COMMODITY REVIEW

METALS

Aluminum.—Output for 1963 increased slightly over that of 1962, reaching a new high for the industry. This increased production continued the rapid growth by the industry over the past decade, during which Norway has become one of world's major sources of primary aluminum. Among the nation's four producers in 1963, the State-owned A/S Årdal og Sunndal Verk remained dominant and produced almost 70 percent of the total.

Extensive expansion plans for the export industry were finalized during 1963. Contracts were signed for the building of three large-scale aluminum plants during the next 2 to 4 years (total reported combined annual capacity 160,000 tons). Two of these new plants will be jointly financed by U.S.-Norwegian interests, and the third will be financed by a consortium of Swiss-French-Norwegian capital. In addition, three of the four existing domestic producers are expanding plant facilities. The total ingot capacity of the industry at the end of 1963 was about 240,000 tons. A projected aluminum capacity of 400,000 tons by 1970 has been mentioned by officials in industry. The Norwegian Government has approved the building of the power facilities for this expansion, and financing is being arranged.

During 1963, as in previous years, most of the aluminum output was exported (85 percent), principally to other European countries and the United States. Over the past decade Norway's most important customers have been the United Kingdom (26 percent), the United States (18 percent), Sweden (14 percent), and West Germany (10 percent). The remaining 32 percent was shipped to a wide variety of countries throughout the world. All aluminum raw materials must be imported since Norway has none. Jamaica and Guinea continued to be the most important alumina suppliers; Greece provided the bauxite.

Consumption within Norway during 1963 increased to almost 30,000 tons. Over half of this domestic consumption was by the country's only aluminum fabricating plant, A/S Nordisk Aluminium Industri, which is a subsidiary of one of the private aluminum producers, A/S

Digitized by Google

Norsk Aluminum Company. Both the fabricating plant and the parent company are doubling their original plant capacities and expect to complete this expansion during 1965 when their ingot and processing capacity will be 28,000 to 30,000 tons annually. The remainder of the domestically consumed aluminum is used by Norway's foundry, alloy, and metalworking industries.

Cadmium.—Cadmium metal is a byproduct of the refining of zinc at the Det Norske Zinkkompani A/S plant. Slightly over 90 percent of the cadmium output is exported, primarily to Sweden. The balance is consumed domestically.

Cobalt.—The nation's total cobalt output is derived as a byproduct of the processing of imported nickel-copper matte. Practically all of this production has been exported, with roughly three-fourths going to the United States. Small quantities of cobalt are contained in some of the country's pyritic ores, but these are not sufficient to justify domestic recovery.

Columbium-Tantalum.—All production comes from a small Government-owned mining operation that was started in 1953 based on markets and favorable price incentives provided by the U.S. stockpiling program. Declining world prices since 1955, when stockpiling was completed, have made the Norwegian operations a losing or near-marginal operation.

An increasing portion of the concentrate have been converted to ferrocolumbium since 1957. Nearly all the exports of both the ferrocolumbium and the concentrate have been to the United States.

It has been reported that further consideration was being given to closing this operation because of the continued operating losses. The Government has reportedly offered this property for sale and will discontinue operations by July 1, 1964, whether or not a buyer is found.

Copper.—The metallic copper output in Norway has been derived mainly from processing nickel-copper matte imported from Canada. This matte is processed at the Falconbridge Nikkelverk A/S, the only significant copper processor in the country. The remainder is blister copper recovered from the processing of domestically mined ores at the largest base-metal-mining operation.

In 1963 there were 12 underground operations, most of them relatively small, mining pyritic ores. Ten of these mines contained copper-bearing ores. Some of the copper was recovered as concentrates within the country, and the balance was exported as copper pyrites and recovered at foreign smelters. Total contained copper eventually recovered from Norwegian ores was almost 14,000 tons in 1963, about the same as in 1962.

Among the operations based on domestic ores, A/S Sulitjelma remained the largest producer. In 1963 their electric smelter and air-blown converter produced over 4,000 tons of 99 percent blister copper. All the remaining mine copper producers process the ores to concentrates, primarily by flotation.

In 1963 the country's entire domestic output of copper and the refined copper recovered from imported matte was exported in the form of concentrate, copper-bearing pyrite, and blister copper. The actual total export of copper in all forms for 1963 was 28,600 tons,

Digitized by Google

of which the electrolytically refined copper amounted to slightly over half. Nearly all the exports were to Western European countries and the United Kingdom; no one country received a particularly large quantity.

Norway's domestic needs are satisfied entirely by imports. In 1963 these imports originated principally in Western Europe and the United Kingdom; Canada and the United States each provided small amounts of copper and copper alloy products.

Iron Ore.—The 1963 output of iron ore increased slightly to a record level. One large, Government-owned open-pit mining operation, A/S Sydvaranger, in northern Norway near the Soviet border, continued to dominate the iron ore picture. During 1963 it produced about three-fourths of the country's output; two underground operations, one of these also Government-owned, provided most of the remaining output. There are some smaller producers whose output was very limited.

As in the past, nearly the entire output of the country's iron ore was in concentrate form. The grade of the ores (32 to 40 percent) was such that they required beneficiation. It was necessary to mine over 3.4 million tons of low-grade ores to produce about 2 million tons of 65 to 66 percent iron ore concentrate.

As in previous years, Norway's export of iron ore concentrate went principally to West Germany and the United Kingdom. Nearly all the exports came from the Sydvaranger taconite operations. No significant changes are anticipated in the trade patterns for 1964, since nearly all these exports are sold in advance to traditional customers on an annual contract basis. The entire 1964 output (estimated at 1.5 million tons) of iron ore from Sydvaranger reportedly had been sold in advance to customers in West Germany, the United Kingdom, Austria, and Norway, at the same price levels as in 1963.

During 1963 Norway's consumption of iron ore held firm at slightly over 700,000 tons. The principal customers for these ores are the domestic steel producers, two of which produce almost all of the country's iron and steel output. The Government-owned steel plant at Mo i Rana continued to obtain its annual needs of about 500,000 tons from Sydvaranger and the Fosdalen iron mine. The private steel producer Christiania Spigerverk, has two mines which supply its entire iron ore requirements of about 120,000 tons annually. The remainder of the domestic iron ore consumption is by the ferroalloy industry.

Ferroalloys.—In 1963 Norway maintained its position as one of the world's largest producers of ferroalloys, with particular emphasis on the silicon-bearing alloys. Ferrosilicon production provided about 40 percent of total output, with the balance divided among ferrochrome, ferromanganese, and silicomanganese, which has shown the greatest increase in use in recent years.

A new ferrosilicon producer, Orkla Metal A/S, began operations in late 1963. Its plant was converted from a pyrite smelter to a ferroalloy production works for economic reasons at the end of 1962. Annual capacity of the new producer will be 25,000 tons. The new plant was Norway's ninth ferrosilicon producer. During the year there were no plant or capacity changes among the four producers of ferrochrome and ferromanganese alloys. The Union Carbide subsidiary,

Digitized by Google

Electric Furnace Products, Ltd., produced over 100,000 tons of chromium and manganese-base alloys and continued to dominate the industry.

The only other ferroalloy producer was a small State-owned facility which converts part of its concentrate output to ferrocolumbium. This operation may be discontinued in mid-1964.

In 1963 the country remained one of the world's leading exporters of ferroalloys. Normally 85 to 90 percent of the ferroalloy production is exported, principally to other European countries, and this market position was maintained in 1963. As in the past, the United Kingdom, West Germany, and Belgium-Luxembourg received the bulk of these exports. Shipments to the United States, which in recent years have averaged about 16,000 tons dropped 54 percent to 7,410 tons in 1963.

Of the raw materials for ferroalloy production, Norwegian mines supply silica and iron ore; all the manganese and chrome ores have to be imported. Ghana continued to be the principal source of manganese ores, with the Soviet Union and the Republic of South Africa as secondary suppliers. The Federation of Rhodesia and Nyasaland and Turkey continued to provide most of the chrome ores.

Iron and Steel.—In spite of the nation's 1963 record level of crude steel output, Norway's major steel producer, the State-owned Mo i Rana steel complex (which provides roughly three-quarters of the country's output) experienced losses estimated at about US$4 million in 1963. Moreover, lesser but still significant losses were projected for the next 2 years. The complex has been in the process of expanding its capacity to about 750,000 tons annually and becoming fully integrated by developing its own iron ore source at the nearby Dunderland deposits. In early 1964 the Government appointed an advisory committee of three experts, two Norwegians and one American to evaluate all aspects of the Government iron and steel operations. All three members of the committee are from private enterprise.

Christiania Spigerverk, the privately operated second major producer whose output is almost totally for domestic consumption, had another successful year of operation. Both crude and rolled steel production reached new highs at or near present capacity levels. Total sales for the firm were also at a new peak of almost US$34 million. Spigerverk, a fully integrated producer, began as a nailworks but by 1963 was operating a complex of divisions and subsidiaries that produced a wide variety of finished products ranging from farm implements to tin cans. It also operated a ferroalloy plant and the largest wire-drawing plant (35,000 to 40,000 tons annually) in Scandinavia. The total number employees of the corporation in 1963 increased to almost 3,200, which is about the same number employed by the Mo i Rana complex.

Output at Norway's other steel plant, Stavanger Electro-Staalverk A/S, a specialty alloy steel producer, increased slightly in 1963 to 26,000 tons.

In 1963 Norway continued to be dependent on imports for most of its iron and steel requirements. Imports for the year were equivalent to about two-thirds of the estimated domestic consumption. Over half the imports in 1963 were as plates and sheets; structural steels

Digitized by Google

made up the second largest import group, and the balance was distributed among the other steel categories. The bulk of these steel imports maintained the country's traditional trade pattern and originated largely in Belgium-Luxembourg, West Germany, and the United Kingdom.

Exports of both pig iron and steel increased. Pig iron shipments expanded to 140,000 tons and steel shipments to almost 190,000 tons. Structural steel and ingots were the largest export categories; the principal customers were Sweden and the United Kingdom.

Lead.—No primary refined lead was recovered in Norway. Output of concentrates came from two mining operations, Bleikvassli Gruber A/S and Bergverkselskapet Nord-Norges A/S, both of which also produced other base metals and pyrites. Over 90 percent of the concentrate output came from the Bleikvassli mine which opened in the early 1950's.

All lead concentrate produced in 1963 was shipped to West Germany for smelting under an arrangement in effect since 1954. The country's needs for lead and lead products were met through imports, except for small tonnages of secondary lead recovered domestically. In 1963 the imports were 11,500 tons of lead and lead products, of which the major portion was lead ingots. Sweden continued to be the principal supplier.

Magnesium.—During 1963 the country strengthened its position as the world's largest exporter of magnesium, increasing its sales almost 16 percent over the 1962 level. All production continued to come from a single plant southwest of Oslo, operated by the major chemical and fertilizer producer, Norsk Hydro-Elektrisk Kvalstofaktieselskabet. The plant, which began operation in 1951 under the impetus of the U.S. stockpiling program, has had a history of continuous growth. Plant capacity at the end of 1963 had been increased to over 19,000 tons, and plans have been made to further expand capacity in 5,000-ton stages. Reports indicate that expansion of plant capacity will continue during 1964.

No basic changes appeared in the modified electrolytic process used in magnesium recovery, so the raw material base of sea water, dolomite mined in Norway, and coal from privately owned West Spitsbergen mines appears more than sufficient to support any foreseeable market demands.

Most of the exports in 1963 continued to go to West Germany for use in the manufacture of components for Volkswagen automobiles. The small remaining exports have gone to other European countries.

Molybdenum.—Norway's entire molybdenum production came from A/S Knaben Molybdaengruber's mine and mill in southern Norway, Western Europe's only significant molybdenum producer. Swedish interests (Avesta Jernverk) control this operation, and nearly all the output was exported to Sweden.

Nickel.—A refinery operated by Falconbridge Nikkelverk A/S accounted for all of Norway's nickel output. This firm is a subsidiary of the Canadian company Falconbridge Mines, Ltd. The Canadian parent company ships its entire smelter output to the Norwegian plant for final processing. The smelter product imported was a matte containing 48 to 50 percent nickel, 28 percent copper, and small amounts of cobalt, selenium, and various precious metals.

Digitized by Google

World markets for nickel during the year declined so much that in late 1963 the Norwegian nickel plant reportedly had an unsold inventory of 8,000 tons. It therefore became necessary to lay off temporarily 140 of its workers, roughly 10 percent of the total labor force. When market conditions improved near yearend, these workers presumably were reemployed.

Nearly all the refined nickel was exported. The United States was the primary customer (about half of the shipments), and the United Kingdom, West Germany, and Sweden received most of the balance. Imports of nickel-copper matte from Canada in 1963 were about 50,000 tons, compared with 60,857 tons in 1962.

Precious Metals.—In 1963, no precious metals were derived in Norway from Norwegian ores. Small amounts of gold, silver, platinum, and selenium were recovered at the nickel refinery of Falconbridge Nikkelverk A/S, which processes nickel-copper matte imported from Canada. Exact amounts of these metals recovered have not been reported, but platinum exports of 13,000 troy ounces were reported in 1962. These are assumed to have originated at the nickel refinery. All platinum exports were in crude form and were destined primarily for the United States and West Germany.

The country traditionally imports both silver and platinum for use of its extensive metalworking industry. Imports of silver in 1963 were almost 2.8 million ounces and originated mainly in the United Kingdom and West Germany. A small export trade in silver has been conducted with Denmark.

Some of the country's pyrite concentrates contain minor amounts of precious metals; these were not recovered in the country.

Tin.—Output of tin in 1963 was derived totally from the processing of scrap, primarily tinplate, at the A/S Stavanger Tinfabrik in southern Norway. This plant can process 20,000 tons of scrap annually. Nearly all scrap treated has been of domestic origin.

Imports of tin and tin alloys for 1963 were mainly as crude tin, while exports were nearly all in the form of solder destined for Sweden. This solder was produced by the Stavanger tin plant, which also produces a variety of aluminum and base metal alloys.

The country's estimated annual domestic consumption of tin and tin alloys is 900 to 1,100 tons, most of which is used in making tinplate for the country's large canning industry.

Titanium.—Norway's titania concentrate output for 1963 was estimated to have increased nearly 10 percent over the 1962 level, but was considerably below the peak output in 1961. Nevertheless, Norway still holds a very important position within the world titanium industry. All titania production continued to come from a single producer, A/S Titania, a subsidiary of the National Lead Company, a U.S. firm. Original mining at this operation was by underground methods, but the development and exploitation of a new, very large ore body (300 to 350 million tons of 17 percent titanium dioxide and 20 percent iron) near the original deposit permitted mining by low-cost open-pit methods. Cost results at this new operation have been so favorable that the underground operations are scheduled to be shut down within the near future, after which all output will come from the new deposit. This changeover was being accomplished in 1963.

Digitized by Google

During the year a 15,000-ton-per-year pigment plant was being constructed at Fredrikstad, adjacent to a small existing plant. This had not come into full-scale operation at yearend. The plant output is to be marketed domestically and within Scandinavia.

During 1963, as in the past, nearly all of the titania concentrates except those consumed domestically, went to the National Lead Company pigment plant at Leverkusen in West Germany. No change is foreseen in this pattern unless a titanium slag plant is built in Norway. Over the past year there have been discussions, full-scale amenability tests, and pilot plant operations for a proposed titanium slag smelter able to treat 600,000 tons of concentrates annually. This plant is to be built in Norway near the present operation. Total capital investment required for such a smelter is U.S.$35 million. Approval of the required power facilities for this smelter was given by the Norwegian Government in June 1963. Owing to the large investment required and the depressed condition of world markets for titanium, no definite action on this smelter proposal was taken by the end of 1963.

Zinc.—Zinc output for 1963 showed a slight increase over that of 1962 but was well below the peak years of 1956 and 1959. The entire zinc production continued to be processed at one of Europe's largest electrolytic zinc plants; this facility is operated by Det Norske Zinkkompani A/S, in which the Belgian firm Royale Asturienne des Mines holds a controlling interest. About 75 percent of the ores treated at the Eitrheim plant were imported, and the remaining 25 percent were from domestic mines.

Seven domestic mining operations recovered zinc concentrates to be further processed at the Eitrheim refinery. The zinc content of domestic ores produced in 1963 was slightly over 10,000 tons. Two companies, A/S Bleikvassli Gruber and Folldal Verk A/S, produced over 60 percent of domestic mine output.

In 1963 a little over three-fourths of the refined zinc output was exported, almost totally to other European countries, Sweden, France, and West Germany continued to be the largest customers.

The import of ores in 1963 was slightly over 80,000 tons; as in the past, Sweden, Australia, Spain, Canada, and France provided the ores.

The country's imports of zinc and zinc products reached a new high in 1963, when 6,000 tons were brought in, primarily from Western Europe. Estimated consumption of zinc and zinc products for the year was 16,000 tons, a 6-percent increase over that of 1962.

NONMETALS

Cement.—The country's three cement plants, which produce almost totally for domestic consumption, had a combined output of 1.4 million tons during the year. This was almost identical with the production of 1962.

Clays.—Norway's clays are suitable for building uses, but the country lacks ceramic-quality clays. Imports of ceramic clays, primarily from the United Kingdom, exceeded 80,000 tons in 1963. Over half of these imports were china clay.

Digitized by Google

Dolomite.—Output of dolomite reached a new high in 1963. All this production was mined by Hammerfall Dolomitbrudd, which is owned and operated by the Norwegian Talc Co., A/S, the leading nonmetallics producer in the country. The major portion of Norway's dolomite consumption is used in the production of magnesium at the Norsk Hydro plant.

Dolomite exports also expanded in 1963; principal customers were Sweden, France, West Germany, and the Netherlands. Adequate dolomite reserves exist to supply the expansion taking place within the magnesium industry and any additional export markets that may be developed.

Feldspar.—The bulk of Norwegian feldspar output was exported, principally to the United Kingdom and other European countries for use in the ceramics industries. Domestic consumption, used primarily in glass and porcelain manufacture, is estimated at 3,000 to 5,000 tons annually. Output was obtained from the mining of pegmatite dikes from which mica, quartz, and other minerals also are recovered.

Fluorspar and Cryolite.—All fluorspar and cryolite used in Norway must be imported, since the country has no domestic sources. Fluorspar is used in the steel, ceramic, and aluminum industries; consumption in 1963 was almost 3,000 tons.

Domestic consumption of synthetic and natural cryolite, which totaled about 8,500 tons in 1963, was used in the country's extensive and growing aluminum industry. Over three-quarters of the cryolite consumed was in synthetic form and was imported from West Germany and Italy. All the natural cryolite has come from Denmark's operations in Greenland, which stopped production in 1962 but had sufficient ore stockpiled to supply present customers for an estimated 20 years at the present rate of consumption.

Graphite.—Output of processed graphite from the country's single producer was nearly 7,200 tons in 1963, a 11-percent increase over that of 1962 and an alltime high. The A/S Skaland Grafitverk quarried and processed about 28,000 tons of 25 to 30 percent ore in 1963 to produce the final product, nearly all of which is exported. The Ever-Ready Co. of London, a large battery manufacturer, owns a financial interest in the Skaland operations and conducts most of the company's export business. Small tonnages of specialty graphites were imported from the United Kingdom and Sweden.

Mica.—The output of mica was derived from the mining of pegmatites. Roughly three-fourths of this production was exported to West Germany, France, and Sweden to be used in the electrical industry.

Scrap mica imported in 1963 came primarily from India. The cheaper unit cost of the scrap mica is the reason for importing it, rather than consuming the domestic output.

Nepheline Syenite.—Production of nepheline syenite, which began in late 1959, expanded sharply in 1963. Output was obtained entirely from an underground mine and a plant operated by A/S Norsk Nefelin, a subsidiary of the major domestic steel producer, Christiania Spigerverk. Most of the nepheline syenite output is exported, but the country's largest porcelain manufacturer consumed some of the

Digitized by Google

output as a raw material for porcelain manufacture replacing feldspar, to which it has superior characteristics. It is anticipated that in 1964 output may reach the rated plant capacity of 40,000 to 50,000 tons.

Phosphate Rock and Other Mineral Fertilizers.—Norway is deficient in minerals from which the three basic fertilizer components(nitrogen, potassium, and phosphate) can be recovered. Thus, the country's requirements for fertilizers must be satisfied by either synthetically manufactured fertilizers or production based on imported fertilizer raw materials. Imports of phosphate ores in 1963 were almost 170,000 tons, a slight increase over those of 1962. Morocco was the primary source; the Soviet Union was the secondary supplier.

Pyrites and Sulfur.—The country's pyrite production in 1963 declined 10 percent, compared with 1962 output. This reduction was primarily due to the end of pyrite processing at the Orkla Metals A/S plant, effective December 31, 1962. This plant, which formerly treated about one-third of the domestic pyrite output, was the country's only source of elemental sulfur. In addition the plant recovered copper. It was converted to ferrosilicon production after its closure as a sulfur and copper operation.

Twelve domestic mines produced pyrites in 1963, all by underground operations. Among these, Orkla Gruber A/S continued to be the dominant factor in pyrite production, with about 40 percent of domestic production. One other operation, the Skoravas mine, was a fairly large producer with an annual output of about 140,000 tons of pyrite concentrates. Other producers were small and most of them also recovered base metal concentrates. One of these smaller mines, Bjorkasen Gruber A/S, totally owned by Swedish interests, reportedly shut down operations at the end of 1963 owing to insufficient reserves and continuing poor marketing conditions for pyrites.

Silica.—The major portion of Norway's quartz output was consumed by the country's extensive ferroalloy industry. High-purity quartz was also produced in small tonnages for use in the domestic ceramic and silicon carbide industries. In addition, about 25,000 tons of electronic-grade quartz was produced and shipped to West Germany, the United Kingdom, and the Netherlands. Small tonnages of semiprocessed, electronic-grade quartz were imported from Sweden and West Germany.

Norway has adequate construction material sands but has to import its entire supply of glass sands and some other specialty sands. Imports of these commodities totaled about 82,000 tons in 1963. Belgium-Luxembourg provided most of the glass sands, which amounted to about 70 percent of the total imports of special-purpose sands. The country exported small tonnages of foundry sands; these were presumably olivine sands, although export statistics do not identify them as such.

Talc and Soapstone.—The country's production of talc and soapstone in 1963 was slightly above that of 1962. Output is exported principally to the United Kingdom, Denmark, and West Germany with the remainder divided among some 20 other countries.

Most of the talc and soapstone is processed into ground form by A/S Norwegian Talc, which operates several quarries and a processing plant at Bergen. This firm specializes in extremely fine grinding

Digitized by Google

(micronizing) of nonmetals of all types. Annual output of all nonmetals from this plant is about 70,000 tons, of which an estimated 40,000 tons is ground talc and soapstone.

MINERAL FUELS

Coal and Coke.—All of Norway's coal output comes from one mining operation on the arctic possession of West Spitsbergen and owned by Store Norske Spitsbergen Kulkompani. Coal shipments from the island, which only has a 7-month shipping season because of ice conditions, amounted to 430,000 tons in 1963; about 100,000 tons was shipped for use at the new coke plant at Mo i Rana. It is expected that domestic consumption of coal will increase considerably when this new Government-operated plant begins operations in mid-1964. The plant will require about 300,000 tons annually of Spitsbergen coals when operating at full capacity.

The Government-operated Kings Bay coal mine on West Spitsbergen was shut down following the 1962 disaster and is not expected to reopen.

Coal and coke imports totaled almost 950,000 tons in 1963, of which 75 percent was coke of various types. The United Kingdom and Belgium-Luxembourg provided most of the coal imports, and the United Kingdom also supplied the bulk of the coke imports. Exports of Spitsbergen coal amounted to over 180,000 tons, or about half the domestic production for 1963. West Germany received 80 percent of these exports and Denmark received the remainder.

Petroleum.—Norway continued to be totally dependent on imports for its requirements of crude oil and petroleum products. Imports in 1962 exceeded those of 1961 by almost 17 percent. This does not represent a similarly high increase in consumption because exports of refined products for this same period were almost doubled. Actual domestic consumption increased 5 percent, comparing 1962 with 1961, and private estimates indicate that 1963 consumption increased almost 8 percent over 1962 levels.

Norway's two refineries, both totally owned subsidiaries of Standard Oil of New Jersey, had a combined annual crude oil throughput of over 17 million barrels in both 1962 and 1963. The refinery at Slagen, completed in late 1960 at a cost of US$30 million, is rated at 40,000 barrels per day and is the largest in Scandinavia. This new refinery processes about 93 percent of the crude oil refined in Norway.

Over half of the current output of domestically refined products, principally diesel fuels and residual oils, is exported to Denmark and Sweden. In 1962 and 1963 this amounted to an estimated 9 million barrels of products. This large export trade has developed since the Slagen refinery came into full-scale operation in 1962.

In the past few years there has been a flurry of exploration activity on the arctic island of Spitsbergen, which is a Norwegian possession. U.S., Soviet, and private Norwegian interests have been conducting independent exploration, but no discoveries have been announced. Plans for oil and gas exploration programs on the Continental Shelf off the west coast of Norway were anounced in mid-1963. This exploration was to be conducted by major U.S., British, and French petroleum concerns.

Digitized by Google

Plans were also reported for a new major refinery to be built in southwest Norway by the Royal Dutch Shell Co. Proposed capacity was 40,000 barrels per day, and estimated completion date was 1967–68. Official Government announcement of its approval has not been reported.

The Mineral Industry of Poland

By Bernadette C. Michalski [1]

POLAND's two leading mineral products are high-rank coals and zinc; output of each accounted for 4 to 4.5 percent of the world's total in 1963. The country also produced 2.2 to 2.6 percent of the world's cadmium, cement, salt, and sulfur during 1963. The significant aluminum, iron and steel, and petroleum-refining industries are based upon imported raw materials, primarily from the Soviet Union.

The mineral industry, including metallurgical and cement operations, contributed about 12 percent to the gross national product and employed 18 percent of the total labor force. Poland's overall industrial growth rate has declined steadily since 1960, when it was 10.9 percent greater than in 1959; in 1963 the rate was only 4.9 percent higher than in 1962.

Factors contributing to the decline of the industrial growth rate were overemployment, low productivity, and inefficient methods of operation. In 1963 employment rose 3.4 percent and gross wages rose 8 percent. In a July resolution, the Council of Ministers attempted to restrict employment, particularly in the construction industries. It was reported that fuels, iron and steel, and sulfur production met the goals for 1963. However, aluminum, electric power, pig iron, rolled products, and zinc failed to meet the 1963 targets.[2]

The leading mineral developments occurred in the fuel industries with discovery of natural gas and possibly petroleum in western Poland, construction of refining and other facilities at Plock, completion of the Friendship pipeline through Poland to the Schwedt refinery in East Germany, development of seven new mines and expansion of nine mines in the Rybnik coal basin, and expanded use of hydraulic coal transportation.

The shortage of iron and steel products, particularly pipe and sheet metal strips, continued through 1963. To alleviate the import burden, construction began on a new cold-rolled strip mill at the Warszawa metallurgical plant and a rolled and drawn pipe unit at the Zawadski plant. A tinning line was completed at Nowa Huta during the year.

Increased electrolytic copper production was attributed to the new electrolytic unit at Legnice. Construction of the new integrated lead-zinc smelter at Miasteczko in Upper Silesia was in progress. Enlargement of sulfur-refining facilities at Tarnobrzeg and operations of a new sulfuric acid plant at Machow contributed to Poland's expanding sulfur-chemical industry.

Digitized by Google

The mineral industry's share of total industrial investments in 1963 was estimated at 23 percent, or $12,000 million.[3] Long-term investments in fuels and iron and steel, which consume the bulk of Poland's mineral foreign exchange expenditure, continued to receive most of the outlays.

PRODUCTION

The output of sulfur, coke, electrolytic copper, and petroleum increased significantly. Petroleum emerged from its slump of 1962, probably through use of better recovery methods. While nearly all reported figures were slightly higher than in 1962, many basic industries did not meet their targets. The zinc industry failed by 4 percent, aluminum by 3 percent, and electric power, pig iron, rolled steel, and pipe by 2 percent or less.

TABLE 1.—Production of selected metals and minerals[1]

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

TRADE

Mineral industry products and raw materials accounted for a quarter of all exports, or Zl1,700 million and a quarter of all imports, or Zl1,800 million, in 1962. While 68 percent of Polish mineral exports were destined for the Soviet bloc and 74 percent of mineral imports were from the Soviet bloc, Polish mineral trade with the free world was significant when compared with that of other bloc nations. The free world in 1962 supplied the following percentages of Polish mineral imports: Tin, 83; alumina, 45; zinc concentrates, 33; copper, 25; and iron ore, 21. In return, the free world received 96 percent of Poland's exports of fuel oil, 55 percent of the aluminum, 50 percent of the hard coal, 28 percent of the metal products, 22 percent of the zinc metal, and 6 percent of the coke.[4] Foreign trade aggravated the balance of payments problem. Exports, particularly of machinery, manufactured consumer goods, coal, and cement, dropped below plan goals. Imports, on the other hand, especially of Western grain, Soviet bloc machinery, coking coal, crude petroleum, petroleum products, and iron ore, exceeded the plan levels.

TABLE 2.—Exports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum	--	4,810	United Kingdom 1,960; Czechoslovakia 1,733; Netherlands 728.
Cadmium	346	350	U.S.S.R. 280; West Germany 45.
Iron and steel:			
Iron ore thousand tons	8	26	Mainly to the Netherlands.

Others—do	46	27	U.S.S.R. 13; East Germany 13.

[1] As reported, apparently lower rank than anthracite.

Digitized by Google

Coal production did not increase as rapidly as domestic consumption, and coal exports to the free world fell 1 million tons in 1963. However, total trade with nonbloc countries increased because better prices were offered outside the bloc. During 1963 Polish representatives showed increased interest in obtaining greater participation in the General Agreements on Trade and Tariffs. By November 1963, the United States restored Poland to most-favored-nation status. However, no appreciable increase in Polish exports to the United States was anticipated in 1964.

COMMODITY REVIEW

METALS

Aluminum.—The Skawina plant, operating near capacity, supplied Poland's total 1963 aluminum production. Construction of a second plant at Konin fell behind schedule and it was doubtful that it would operate in 1964 as planned.

The industry depended on imported bauxite and alumina for its raw material. To ease the import burden, extensive research was conducted for an economically feasible means of alumina extraction from coal ash such as that produced by the Konin thermal power plant, and clays.

Cadmium.—Polish cadmium production was a byproduct of zinc-lead ore mining and processing operations. Production for 1963 was estimated at 420 metric tons, 80 percent of which was exported.

Copper.—The development of the Legnica-Glogow area, to include copper mining and processing facilities as well as electric power, continued through 1963 and represented one of Poland's largest investment outlays. When the area is fully exploited it should provide Poland with sufficient copper for domestic requirements and an exportable surplus. In view of the copper shortage in the Soviet bloc, intensive efforts were being made to meet the scheduled plan. At yearend, two mines were under development in the area, Lubin and Polkowice I. Both were scheduled to begin production in 1966, reaching full capacity by 1970.

The increase of electrolytic copper output to 29,600 metric tons in 1963 was attributed to an additional refining unit placed in operation at the Legnica copper plant.

Iron and Steel.—Domestic iron ore production satisfied only a quarter of industrial demand. Dependence upon iron ore imports, which amounted to 8.8 million metric tons in 1963, was expected to increase because of expanding steel facilities. In 1963, Zl5,600 million was invested in the iron and steel industry, of which Zl3,600 million was slated for new construction and Zl2,000 million for modernization and reconstruction of plants in Silesia.[5]

In 1963 a new electrolytic tin plating division of the Lenin metallurgical plant in Nowa Huta, with an annual capacity of 20,000 tons, was put into operation. Its 1963 output was 10,000 tons. The 9th

Digitized by Google

and 10th batteries of ovens for producing coke opened at the Lenin plant.[6] Other new installations included a cold-rolled strip mill at the Warszawa metallurgical plant, a 200-ton-capacity open-hearth furnace at the Labedy metallurgical plant, a wire mill of 180,000-ton capacity (location unreported), and two open-hearth furnaces at the Zawiercie metallurgical plant. The first stage of a rolled and drawn pip unit was completed at the Gen. Swierczewski plant in Zawadzki; the unit was to have a rated capacity of 50,000 tons of drawn and 25,000 tons of rolled pipe when completed at the close of 1964.

During 1963 the following metallurgical plants were reportedly under some degree of modernization: Batory, Pokoj, Jednosc, and Bierut. Measures taken by the Polish iron and steel industry to alleviate the chronic shortage of iron and steel products were expected to be reflected by lower imports in 1964.

Lead and Zinc.—Poland operated at least seven zinc-lead mines in 1963, yielding 2.5 million metric tons of ore. An exporter of lead concentrate and importer of lead metal, the nation appeared to lack adequate smelting facilities; total annual capacity was estimated at less than 45,000 tons.

Production of zinc-lead ores was inadequate to supply Poland's zinc smelters and refineries; hence large quantities of concentrates were imported. Zinc output in 1963 increased by only 300 tons and failed to meet the planned goal by 4 percent. Zinc exports for 1963, totaling 89,000 tons, were nearly a third greater than in 1962.

A rectification column for obtaining zinc dust of high purity (95 to 98 percent) was put into operation in the Silesia zinc plant in Katowice-Welnowiec in early 1963.

Construction continued on the new integrated lead-zinc smelter at Miasteczko in Upper Silesia. Started in 1962, the plant is expected to begin production in 1966. Plant capacity is not known, but the Imperial smelting process will be employed. Facilities will include a sintering unit, an acid plant, and Waelz kilns. Cowper-Siemens stoves will be used to preheat the blast air.

NONMETALS

Bentonite.—Large commercial deposits were reported near the Radzionkow coal mine. Construction of a processing center near the deposit was being considered in 1963.

Cement.—Production in 1963 increased slightly over that of 1962, but failed to meet the planned goal. A cement plant at Dzialoszyn neared completion at the close of the year. By 1964, it should reach capacity of 1 million tons annually; 700,000 tons would be portland cement.

Kaolin.—Poland's first kaolin mining and processing installation at Nowogradziec near Boleslaw opened in 1963.

Lime.—In spite of abundant limestone reserves, the Poles reported a shortage of agricultural and metallurgical lime in 1963. At the close of the year, five new lime kilns went into operation at the Gorozdzach plant where capacity totaled 180,000 tons of lime yearly.

[6] The amount of coke used per 1 ton of pig iron for Poland as a whole decreased from 932 kilograms in 1962 to 918 kilograms in 1963.

Digitized by Google

Sulfur.—Expansion of sulfur mining and processing facilities at the Tarnobrzeg deposit included work on a second plant for processing sulfur ore. The first stage was to be completed and produce 100,000 metric tons of pure sulfur in 1964. In mid-1963 a new sulfuric acid plant went into operation at Machow. The plant is expected to raise Poland's total sulfuric acid production to 1 million tons in 1964.

MINERAL FUELS

Coal.—Although Poland's coal output target for 1963 was reportedly overfulfilled, a shortage occurred late in the year. Apparently, coal consumption increased more rapidly than production. The additional fuel necessitated by a severe winter, growth of coal-consuming industries, and continued inefficient coal burning were contributing factors to the shortage. The imbalance was corrected by a cut of 1 million metric tons of hard coal exports to the free world. Extensive mine development and expansion activities were undertaken in attempt to balance future output with consumption and export programs.

Development began on the Pniowek coal mine, which will be Poland's largest. According to plan the mine will produce 20,000 tons of coking coal per day.[7] Coal waste was cut by construction of a waste processing plant at the Makoszowy coal mine and a similar plant, to be operational in 1964, at the Dymitrow mine. In 1963 seven new mines were under development and nine were expanded in the Rybnik coal basin. A 50-unit coking battery with a rated capacity of 950 tons of coke per day went into operation at the Walenty coke plant in Rudzie.[8]

Polish coal transportation difficulties shall be slightly eased by the introduction of hydraulic coal pipelines. The pipeline connecting Boleslaw Smialy mine with the Laziska power station began operation in 1963. About 1,700 tons of coal flows daily through this pipeline. Another larger pipeline, in the planning stage at year end, will transport coal about 200 miles from Silesia to Nowy Korczyn.

Petroleum and Natural Gas.—With 1963 crude output only 200,000 metric tons, Poland was an insignificant producer of petroleum. Oil developments in 1963 included the discovery of a potential field in Zielona Gora, western Poland, expansion of refinery capacities to process imported crudes, and extension of the Friendship (Druzba) pipeline about 500 miles from the U.S.S.R. through Poland. Expanding refinery capacity failed to keep pace with increasing product consumption, and imports continued to rise, reaching 2.8 million metric tons in 1963. With the Czechowice refinery operating at increased capacity of 450,000 metric tons in 1963 and opening of the Plock refinery in 1964, Poland will produce a greater percentage of its requirements; however, it is doubtful that domestic refinery production will reach the planned 75 percent of product requirements by 1965.

Poland processed nearly 35,300 million cubic feet of natural gas in 1963. Growth in gas output may continue as the result of discovery

Digitized by Google

of new commercial deposits in Nowa Sol. Construction began on a gas refinery in Poznan; upon completion, it should have a capacity of about 8.5 million cubic feet per day.

A 65-mile gas pipeline connecting Przemysl to Jaroslaw was completed in 1963. The entire pipeline (390 miles), scheduled for completion in 1965, will supply nitrogen plants in Pulawy with natural gas from the U.S.S.R. and from domestic deposits in Przemysl.

ELECTRIC POWER

Although it reportedly failed to fulfill its production goal for 1963, the electric power sector made notable gains over the previous year, attaining 37 billion kilowatt hours. The use of brown coal in producing electric energy increased from 9 percent in 1962 to 15 percent in 1963. Two additional turbine generators, of 200-megawatt capacity each, were put in operation at Turow, raising the total capacity to 800 megawatts by the close of 1963. The Konin coal-burning powerplant, also under expansion, attained a capacity of 590 megawatts in 1963.

The Mineral Industry of Portugal

By Anton W. T. Wei [1]

THE MINING and mineral processing industry apparently accounted for about 5 percent of the gross national product in 1963. The mining sector has been relatively stagnant showing little change during the past decade. Mining provides employment to less than 1 percent of the total labor force of 3 million. In 1962 the Portuguese Government formed a commission to study the mining industry and to make recommendations for its reorganization and improvement; the commission continued the investigation in 1963.

Considerable progress, however, has been made in the mineral-processing sector. Output of refined petroleum, pig iron, steel ingots, ferroalloys, and chemical fertilizers all increased in 1963 from the levels of the previous year. The production of ferroalloys, begun in significant quantities in 1962 to supplement the operations of the first integrated steel plant in the country, reportedly increased 67 percent. Production of chemical fertilizer increased about 22 percent in 1963. In prior years, Portugal had exported about a quarter to a third of its annual chemical fertilizer output.

SOURCE MATERIAL

Production data for Portugal are obtained from the official Portuguese Estatística Industrial of the Instituto Nacional de Estatística and foreign service despatches from the U.S. Embassy in Lisbon. Trade data are derived from official Portuguese trade publications. Information on pertinent developments in the minerals industry also comes from foreign service dispatches of the U.S. Embassy.

PRODUCTION

Mine output in 1963 totaled roughly the equivalent of US$40 to US$45 million, based on preliminary and incomplete data. About two-thirds of this mine output was nonmetallic minerals and construction materials. Pyrites, coal, tin, and tungsten continued to be the ranking minerals produced in Portugal. Inclusion of the processing sector raised the 1963 mineral output value considerably above US$100 million. The most important of the processed mineral commodities were cement, iron and steel, and refined petroleum, each of which accounted for more than US$20 million in production value in 1963.

[1] Preliminary.
[2] Data not available.
[3] Officially reported mine output, including copper contained in some cupriferous pyrites produced.
[4] Estimate.
[5] Quantity believed to be limited.
[6] Excludes mixed concentrates.
[7] Revised figure; supersedes that given in commodity chapter, volume 1.

TRADE

Overall trade statistics for 1963 are not yet available, but in 1962 mineral exports totaled the equivalent of US$28 million and imports amounted to roughly US$130 million. These figures represented about 8 percent of the total exports of Portugal for the year and 22 percent of its total imports. More than 40 percent of the value of 1962 mineral imports was accounted for by petroleum and its products, and iron and steel accounted for about a third of the total.

The mineral export position was considerably strengthened towards the end of 1963 when world prices of tungsten and tin showed a marked improvement, and the outlook for pyrites became more encouraging. These three commodities account for an important share of the total mineral exports of the country.

Signing of a contract by the United States Steel Corp. to deliver 200,000 metric tons of metallurgical coke to the Portuguese National Steel Mill (Siderurgia Nacional) was reported in early 1963. The first shipment under this contract was reported to have arrived in April. According to the latest trade information, the United Kingdom, as in prior years, supplied the major part of coke imports in 1963 which totaled about 210,000 tons. Imports from the United States during the year amounted to only 9,000 tons and did not arrive until May. Presumably, the United States Steel contract represented a triangular agreement whereby metallurgical coke was to be delivered to Portugal by United Kingdom suppliers in return for steel shipments from the United States. The total contract represented roughly the annual coke requirement of Siderurgia Nacional. Siderurgia Nacional requirements for foreign iron ore were covered by an agreement signed in April with the Companhia Vale do Rio Doce of Brazil. While the immediate contract called for the supply of only 10,000 tons of Brazilian iron ore, a protocol signed at the same time provided that

Digitized by Google

the Brazilian company would furnish all imported iron ore needs of Portugal. It was estimated that roughly 80,000 to 100,000 tons of imported ore would be needed to supplement the 250,000 tons of domestic output in 1963.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum, unwrought and wrought	55	66	Italy 31; United Kingdom 21; Angola 9.
Arsenic, white	78	1,117	United Kingdom 300; Spain 215; Federation of Rhodesia and Nyasaland 180; Italy 171.
Beryl	(1)	44	All to United States.
Copper:			
Ore and concentrate	2,277	2,136	West Germany 1,543; United States 593.
All other forms	635	565	Italy 497.
Iron and steel:			
Iron ore	95,041	99,508	United Kingdom 66,227; Belgium-Luxembourg 28,161.
Pyrites, roasted	104,323	29,373	West Germany 25,353; Netherlands 3,600.
Scrap	16,656	15,019	Japan 8,580; Italy 4,039; Spain 1,220.
Pig iron and rough castings	15,032	10,177	Italy 9,444; Israel 600.
Ferroalloys:			
Ferrosilicon	1,002	2,411	Belgium-Luxembourg 1,194; West Germany 910.
Other		26	All to West Germany.
Steel ingots and equivalent primary forms.	161	48,598	Spain 33,796; Israel 12,497.
Tubes, pipes and accessories	1,668	3,473	Mozambique 2,253; Angola 472; West Germany 226.
Other semimanufactures	4,348	1,936	Angola 903; Mozambique 244; Turkey 134; Sweden 105; Portuguese Guinea 104.
Lead, unwrought and wrought	29	27	Angola 11; Mozambique 9.
Manganese, ore and concentrate	2,008	880	All to Netherlands.
Nickel in all forms	5	2	All to Italy.
Platinum and platinum-group metals, unwrought and wrought.	grams	10,467	United Kingdom 10,437.
Silver, unwrought and wrought.	grams 10,000	25,000	Angola 20,000.
Tantalum, ore and concentrate	41	43	All to United States.
Tin in all forms	long tons 987	910	United States 709; Netherlands 69; West Germany 50; Angola 24.
Titanium, vanadium and zirconium, ore and concentrate.	(1)	50	Mainly to Netherlands.
Tungsten, ore and concentrate	2,626	2,041	United Kingdom 792; United States 671; Netherlands 224; Japan 180.
Zinc, unwrought and wrought	113	5	Cape Verde 3; Mozambique 2.
Nonmetals:			
Barite	611	5	All to United Kingdom.
Cement, hydraulic	40,108	179,430	Spain 158,223; Gibraltar 11,536; Cape Verde 4,117.
Clays:			
Kaolin	19,478	15,739	Italy 10,950; France 4,400.
Other	191	297	Angola 153; United Kingdom 100.
Diatomaceous earth	310	288	United Kingdom 160; Netherlands 89.
Fertilizers and fertilizer raw materials:			
Nitrogenous	215	491	United Kingdom 448.
Phosphatic:			
Superphosphates	83,359	56,216	South Korea 32,700; Indonesia 10,825; Cyprus 7,381.
Other	4,630	9,645	New Zeland 9,568.
Potassic	208	130	Mozambique 43; St. Thomas and Principe Islands 37; Angola 36.
Flint	1,930	2,767	Belgium-Luxembourg 1,208; Mozambique 1,056; Angola 264.
Gypsum	433	228	Angola 124; Mozambique 79.
Lime, hydraulic	1,232	1,168	Mozambique 725; St. Thomas and Principe Islands 258.
Natural pigments	42	64	Angola 33; Mozambique 16.
Pyrites, unroasted	265,168	292,082	Belgium-Luxembourg 180,572; France 38,550; West Germany 36,425; Netherlands 35,135.
Quartz and quartzite	(2)	3,455	Mainly to Italy.
Salt	416	2,306	Bunkers 2,280.

COMMODITY REVIEW

METALS

Iron and Steel.—Siderurgia Nacional is the only integrated steel mill in Portugal and possibly its only crude-steel producer. Siderurgia Nacional was completed in August 1961 with a reported annual capacity of 250,000 to 300,000 metric tons of steel; it employs the Linz-Donawitz (L-D) process of steelmaking. Output continued to increase in 1963 as production at the plant approached designed capacity. The Portugal steel brokers had anticipated the significant increase in tariff, which was applied when Siderurgia Nacional began operations, and had accumulated a sizable inventory of imported steel. As stocks held by brokers were drawn down, the orders placed with Siderurgia Nacional began to increase; yearend inventories showed a gain in orders placed from 118,000 tons in 1962 to 154,000 tons in 1963. Nevertheless, while income in excess of normal operating expenses, including interest charges, returned a net of approximately US$3 million, the annual report of the company for 1963 shows that after amortization charges the deficit for the year amounted to nearly US$8 million.

The first cold-rolled strip-steel mill in Portugal, designed and equipped by the United Kingdom firm of Bromford Iron and Steel Co., Ltd., was being built in 1963 for F. Ramada Acos e Industrious, S.A.R.L., at Ovar near Oporto. Schedule for completion was the end of 1964; the £385,000 plant was to produce about 15,000 metric tons of cold strip and a similar quantity of bright drawn bar annually.

Tin and Tungsten.—By curtailing output and by retrenchment, Beralt Tin and Wolfram, Ltd., the major tungsten producer in Portugal, was able to achieve a marked reduction in its wolfram-production cost and to partially compensate for the low demand in the world

Digitized by Google

tungsten market. Meanwhile, the United States firm, Metallium Corp., maintained a limited but regular production of tungsten concentrates. In the early part of the year it had plans to acquire additional wolfram deposits and to place itself in a position to greatly increase output, should a more active demand develop at higher prices.

Despite rising world prices, the tin output in 1963 showed a marked decline from the 1962 level. The Beralt firm, also a small tin producer in the country, was reported to be actively engaged in exploring new tin areas during the year.

MINERAL FUELS

Coal and Coke.—Portugal coal and coke consumption in 1963 totaled 886,000 and 258,000 metric tons, respectively, compared with 847,000 and 223,000 tons in 1962. Except about 34,000 tons of domestically produced gas plant coke, all the coke consumed consisted of imported metallurgical grade material. The market for coal in the electric-power-generating industry is unusually small, as the major part of the facilities consist of hydroelectric plants, and many of the thermal plants are oil fired. In 1963 the estimated consumption of 100,000 tons of coal probably provided only about 5 percent of the total quantity of power generated.

Petroleum.—As in prior years Portugal did not produce crude petroleum. Output from the only refinery, the SACOR plant at Lisbon—operating on imported crude oil—continued to increase during the year. Construction of a second refinery and petrochemical adjunct, planned for the northern coastal region of Oporto, had not yet begun nor had it been announced which foreign firms would participate in the capitalization. Portuguese firms selected to participate in this project, according to the Minister of Economy, were SACOR, the principal domestic participant; Sociedade Nacional de Petroleos SONAP, a prominent distributor of petroleum products; and the Companhia União Fabril, the leading industrial concern in Portugal. A large part of the production from this refinery would be for export.

A new storage area of Shell Portuguesa at Matosinhos was completed in April 1963. The new installation comprised 2 warehouses and 11 storage tanks, having a combined capacity of about 283,000 barrels; it cost 46 million escudos and is 1.5 kilometers from the Port of Leixões. It is connected to the port by a double pipeline.

Portuguese official statistics indicate that domestic consumption of petroleum products in 1963 totaled approximately 1.4 million tons. In the meantime, imports of crude, fuel, and other petroleum products continued to be a major drain on the financial resources of the country, totaling 1.12 billion escudos through November.

The Mineral Industry of Rumania

By Roman V. Sondermayer [1] and K. P. Wang [2]

RUMANIA's industrial status is characterized by a well-established petroleum industry and a new large steel complex in process of construction. In 1963, crude oil output ranked second in Europe, to that of the U.S.S.R., although it was equivalent to only about 6 percent of Soviet production. The Rumanians were aiming at an additional 5-million-ton annual steel capacity by 1970, nearly twice the 1963 output. The metallurgical and manufacturing base was being expanded, but the domestic raw-material position did not show great improvement. Rumania's leading mineral products, with output in percentages of 1963 world totals, were as follows: Manganese, petroleum, salt, and cement, 1 to 1.5; and lead, iron ore, pig iron and steel, mercury, and coal, 0.3 to 1.

Rumania does not report industrial product and gross national product (GNP), except by way of indices. Mineral and metal output value in 1963 was about 15 percent more than in 1962. The share of the mineral industry in the 1963 GNP was roughly 18 percent. The 223,000 workers employed in the mineral industry during the year represented about one-sixth the total for all industry. Minerals were important in Rumania's international trade, particularly refined petroleum exports.

During 1963, special efforts were made to raise the efficiency of established mineral operations, both by improving productivity and reducing consumption of materials and supplies, two areas which presented numerous problems to the industry in the past. Considerable funds were also spent in capital construction. Mineral industry investments in 1963 amounted to 8,394 million lei [3] as compared with 7,567 million lei in 1962. The bulk of the investments went into the fuels industry (particularly petroleum) and iron and steel industry.

No major event occurred in the oil industry, Rumania's premium industry, or in the natural gas and coal industries. The main activity in the fuels area during 1963 was centered on improvement and development of existing facilities.

The most important developments in the mineral field took place in the ferrous and nonferrous industries. Highlights in 1963 included the opening of a sizable iron mine and commencement in construction of a large steel mill in the Danube Delta port of Galati, commissioning of new blast furnaces in Resitza and Hunedoara, continued construction of the Copsa Mica lead-zinc smelter in Transylvania, discovery

of the Sommova lead-zinc deposit in Dobrugea, and ground breaking in building a new aluminum plant at Slatina.

PRODUCTION

Output of most mineral and metal products in Rumania has increased every year from 1959–63. However, increases in production of petroleum, the country's leading mineral product, have been relatively modest.

During 1959–63, output of iron and steel products roughly doubled, with important gains made in 1963, particularly for iron ore. No official statistics are available for nonferrous base metals, but apparently copper output remained nominal and lead-zinc output rose only slightly. Construction of lead-zinc facilities indicates that more refined metals will be produced in the future.

In the same 5-year span, a whole new nitrogenous fertilizer industry was created, presumably based primarily on natural gas. The phosphatic fertilizer industry doubled in size, using Soviet apatite. Salt output also nearly doubled. Cement production in 1963 was about one-fifth more than in 1959. The coal industry expanded about one-fourth.

TRADE

General information is available on the overall mineral trade of Rumania; however, no breakdown on destination or origin is reported. During 1963, exports of refined petroleum constituted about 60 percent of output. Import statistics of the U.S.S.R. indicate that about one-third of Rumania's exports went to that country.

Rumanian-Soviet trade, derived from official figures of the U.S.S.R., shows some trends regarding Rumania's overall international trade. Aside from petroleum, the country exported some cement, certain steel products, and refined lead.

Digitized by Google

Imports reveal interesting facets of the Rumanian mineral economy. There has been a shortage of domestic iron ore, ferroalloys, some rolled steel products, aluminum, and copper. The country has been totally dependent upon imports for phosphatic raw materials and has been somewhat deficient in coking coals and coke. Mineral and metal products as a whole have been very significant in Rumania's overall trade.

COMMODITY REVIEW

METALS

Iron and Steel.—A billion-dollar 5-million-ton steel complex at Galati, scheduled for completion in 1970 after installing six key projects, was still under construction toward the end of 1963, with most of the infrastructure like office buildings, workshops, roads, and rail sidings already completed. Many Western firms were competing for contracts to build different parts of the plants. A Franco-British firm was at work on a 2-million-ton hot-rolling mill. The Soviet Union made commitments to furnish certain equipment for a hot-rolling mill and a blooming and slabbing mill. They also promised future supplies of iron and coal, but Rumanian officials were looking into alternate raw material sources, such as iron ore from Brazil and India and coking coal from the United Kingdom and the United States. Plans call for the use of oxygen converters, but these apparently will not be supplied by the U.S.S.R.

During 1963 the iron mine at Galati started production. The increase of Rumania's iron ore output of 32 percent over that in 1962 can be attributed to this development.

Hunedoara and Resitza retained their positions as Rumania's leading iron and steel centers. Both plants were being reconstructed during 1963. Hunedoara was rated at about 1-million-ton annual capacity, with a sinter plant, two 700-cubic-meter blast furnaces, six 180-ton open-hearth furnaces, blooming mill, heavy and medium section mill, and pipe mill.

Resitza also produced ferroalloys from the manganiferrous iron ore mined at Banat. Rumania produced enough manganese ore not only for internal iron and steelmaking use but also for export.

Nonferrous Metals.—Rumania's leading nonferrous mining centers, with mostly complex ores containing mainly precious metals and lesser values in base metals, are in Maramures and northern and southern Transylvania. Little is known about specific details. For the country as a whole in 1963, it is estimated that about 390,000 ounces of gold, 650,000 ounces of silver, 12,000 tons of mine lead, 5,000 tons of mine zinc, and a few thousand tons of mine copper were produced. At Baia Mare, a copper plant of 40,000 tons annual capacity is under construction. The electrolytic unit capacity will be 20,000 tons per year. In recent years, the Sasar, Baia de Cris, and Baia Sprie mines in Maramures have been mentioned as prominent producers of precious and base metal ores. The discovery of the Sommova deposit in Dobruja during 1963 may lead to greatly increased production of lead-zinc. A plant to produce 27,000 tons of lead and 23,000 tons of zinc annually was scheduled for completion in 1964.

Apparently, no zinc smelter exists in the country as yet, and the zinc concentrate produced is presumably exported. Two lead smelters were operating in 1963, providing even a little surplus for export. The Baia Mare lead smelter and refinery at Firija and Baia Sprie is about 5,000 tons in annual capacity. The Phoenix sulfuric acid and lead smelter at Baia Mare near Lucaci has about the same capacity.

The most interesting news about lead-zinc smelting, however, con-

Digitized by Google

cerns the Copsa Mica integrated lead-zinc smelter being constructed in Transylvania with British help using the Imperial Smelting Process. Although capacity is not known, the plant is expected to begin production in 1965. The Power-Gas Corp. and Huntington Herberlein Co. have been awarded a contract by Masinimport Rumania. The British contract covers equipment and services valued at 2 million British pounds, about two-fifths of the entire cost. There will be sinter, acid, and twin-condenser furnace plants. A copper matte will be separated from the crude lead, which will be sent as ingots to the refining plant.

Bauxite was being produced at declining rates, mainly from the Lorau mines in western Rumania; part of the output was consumed as filter medium by the oil industry and possibly some was exported. The 50,000-ton new aluminum plant at Slatina in the Arges region, built with French help by the firm Pechiney, was being readied for production by 1965. Also under construction is a plant at Oradea, which is expected to produce 120,000 tons of aluminum annually.

The mercury production center in 1963 was Dosului in western Rumania, which probably had ore reserve difficulties. Chromite output, roughly 13,500 tons in 1963 and largely from deposits near Dubova, fulfilled most of Rumania's needs.

NONMETALS

Few details are known about the many nonmetals produced in Rumania, but output was of little importance by world standards. The cement industry operating about 15 plants produced at a relatively stable level in 1963. Salt output, from at least seven rock salt deposits in various parts of the country, continued to rise. Pyrite recovered from nonferrous ores provided most of the sulfur for the country's sulfuric acid production during 1963. Fertilizer production rose markedly, with Soviet apatite as the main imported raw material. A magnesite mine was opened for the Hunedoara steel plant in recent years. Possibly 100,000 tons of gypsum was produced. Talc mines were operating at Lelese and Cerisor in western Rumania. Other products include mica, graphite, diatomite, bentonite, and kaolin.

MINERAL FUELS

Rumania stressed oil development during 1963, in contrast to few undertakings in coal. Exploratory oil drilling was stressed, although some development of existing fields also took place. Between 300 and 400 wells were drilled during the year, more than twice as much by rotary drills as compared with turbodrills. The trend in exploration was to tap deeper reservoirs of more than 9,000 feet.

About 5,000 wells were operating in 1963; daily well output from old fields like Baicoi was below 2 tons, whereas that from the new field of Ciuresti was around 22 tons. The new oil fields in the pre-Carpathian depression located west of the old Ploesti and Moldavian fields and the areas south of this depression accounted for about two-thirds of Rumania's oil output. Most discoveries were made in the early 1950's, and finding new oil fields has become more difficult in recent years.

Digitized by Google

The Rumanians stressed both water injection and gas repressuring to maintain underground pressure. Lenticular sands and complicated tectonic conditions limited the effectiveness of such measures. Electronic devices for controlling oil production were introduced with centralized instruments already reportedly installed for about 100 wells.

Rumania's crude oil was processed in 10 refineries, the 6 larger ones having a combined annual capacity of nearly 12 million tons. The country exported slightly more than half of the refined petroleum produced. Ploesti was the main refining center with eight plants. A new center was being developed at Onesti-Borzesti. Recently, a new catalytic cracking plant and an aromatic plant were completed.

Several petrochemical plants were operating in the country. Fagars and Victoria were producing nitrogenous fertilizers and plastics. The Turda Rizanov Onesti, Borzesti, and Savinesti are expected to be completed or expanded shortly. Part of the equipment for petrochemical plants was made locally and part imported from Soviet Ekonomicheskoy Vzayimopomoshchi (SEV) [4] countries.

The Mineral Industry of Spain

By Taber de Polo [1]

VALUE of mine production in Spain suffered a small decline in 1963 from the US$264.7 million recorded for 1962; however, preliminary information is not sufficiently complete to determine the magnitude of this decline. Complete information on the value of production from metallurgical plants and other mineral processing facilities are not available, but in recent years the mineral industry as a whole has contributed progressively smaller shares of the gross national product (GNP) each year; in 1961 its contribution was about 1.6 percent, and this apparently declined to not over 1.5 percent in 1962.

Spain has appreciable reserves of iron ore, pyrites, potassium salts, zinc, lead, and mercury, and each of these commodities has been produced in sufficient quantity to contribute significantly to Spain's export trade. In spite of these exports, however, Spain's balance of trade in mineral commodities has not been favorable; the value of mineral imports exceeded that of exports by US$63 million in 1963.

Other mineral products produced in quantity of significance to the national economy include iron and steel, aluminum metal, refined copper, silver, cement, limestone, coal, and petroleum refinery products.

The Government's 4-year economic and social development plan scheduled to go into effect on January 1, 1964, will be of significance to the mining industry with a potential long-range impact. The overall objective of the plan is a 6 percent annual rise in GNP. Public investments totaling US$5.6 billion are planned, some of which will help modernize certain sectors of the mining industry. The plan encourages the consolidation of the numerous small firms engaged in the production of some commodities such as coal and iron ore. Continued liberalizing of control over foreign investments is expected to help finance modernization of some mineral industry operations.

Some specific objectives for improvement in the minerals industry are—

1. Increased production of coking coal.
2. Consolidation of some of the 222 small companies engaged in iron extraction.
3. Introduction of up-to-date techniques in iron and steel metallurgy.
4. Consolidation and modernization of the numerous small steel mills.
5. Reduction of production costs of iron pyrites and consolidation of small companies.

[1] Foreign mineral specialist, Division of International Activities.

Digitized by Google

6. Local consumption and export of fertilizers based on sulfuric acid (from pyrites).
7. Consolidation of some of the more than 200 lead and zinc mines in operation.
8. Increased exports and decreased imports of aluminum.
9. Association with large foreign aluminum companies.
10. Enlargement of existing copper smelting operations.
11. Promotion of national production of lead concentrates.
12. Renewal of equipment in mercury mining industry.
13. Replacement of 50 percent of cement production equipment.

PRODUCTION

In 1963, although there was a further slight decline in total value of mineral production, some commodities important to the economy registered gains. Zinc production increased by almost 18 percent compared with 1962 figures; potassium salts showed a slight increase and production of most of the metallics showed a decline.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Aluminum:					
Bauxite	7,659	2,573	5,594	6,047	(1)
Aluminum metal	22,642	28,740	37,648	41,688	43,529
Aluminum alloys	8,898	3,536	10,698	7,155	(1)

Asphalt do	(4)	158	185	249	264
Other do	(4)	20	19	19	21

[1] Data not available.
[2] Revised figure; supersedes that given in commodity chapter, volume 1.
[3] Includes basalt, diabase, fonolite, granite, ophite, porphyry, and trachyte.
[4] Comparable data not available.

TRADE

Preliminary statistics indicate that the value of mineral and mineral product exports in 1963 was slightly over US$27 million, about US$1 million less than in 1962. In terms of value mineral exports consisted largely of iron ore, pyrites, potassium salts, zinc, lead, and mercury. Other export commodities included salt, marble, and barite. The value of mineral imports was about US$90 million, or roughly US$15 million higher than in 1962. Significant imports include phosphates, cement, asbestos, manganese, copper ores, concentrates and scrap, tin ore, and bituminous and anthracite coal.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Unwrought and scrap	3,998	10,720	United States 5,500; Yugoslavia 1,650; Poland 1,600.
Wrought	4,269	3,561	South Viet-Nam 1,336; United States 1,284; Bulgaria 500.
Copper, all forms	456	[1] 122	Belgium 72; Colombia 30.
Gold, semiwrought and troy ounces wrought.		[2]	All to West Germany.
Ilmenite	19,270	24,636	France 9,550; Italy 9,100; Netherlands 5,869.
Iron and steel:			
Iron ore	1,067,127	1,188,441	West Germany 619,245; United Kingdom 216,030; France 141,960.
Roasted pyrites and sinter	1,801,134	777,356	United Kingdom 347,510; West Germany 316,541; Netherlands 51,385; Belgium 47,736.
Scrap	13,474	132	Italy 100; South Viet-Nam 29; France 3
Pig iron and castings	287,679	144,613	Japan 38,719; United States 36,148; Italy 27,680.
Ferroalloys:			
Ferrosilicon	11,852	9,856	United Kingdom 5,047; West Germany 3,084; Japan 1,500.
Other	5,877	5,792	United States 2,600; West Germany 1,545; United Kingdom 1,336.
Steel:			
Ingots and semimanufactures	[3] 239,360	[3] 63,424	West Germany 18,428; France 12,057; Japan 11,626; Turkey 7,693.
Semimanufactures	5,762	8,644	Turkey 2,240; Chile 1,378; France 911; Brazil 779.
Lead:			
Ore and concentrate	1,184	542	United Kingdom 292; West Germany 200; France 50.
Lead and lead alloys, unwrought	36,369	29,233	United Kingdom 9,400; United States 6,406; Italy 4,671; Switzerland 3,000.
Lead, wrought	40	154	Italy 89; Andorra 30; Finland 15; Turkey 11.
Manganese:			
Ore and concentrate	22,802	6,728	West Germany 4,978; France 1,000; Italy 750.
Mercury, 76-pound flasks	48,095	45,891	United States 11,139; West Germany 9,747; United Kingdom 6,875; India 6,788; France 4,148.
Zinc:			
Ore and concentrate	30,129	29,590	Belgium 9,581; Netherlands 8,586; France 7,472.
Unwrought and scrap	22,218	23,846	West Germany 5,600; France 4,800; United States 2,870; Portugal 2,245; Italy 2,119.
Wrought	80	132	Colombia 100; Portugal 14.
Other metallic ore minerals [4]	782	296	Canada 89; United Kingdom 69; Japan 45.
Other metals [5]	[6] 137	217	United States 200; Belgium 5; France 5.
Nonmetals:			
Barite	36,514	40,095	United States 15,306; Italy 13,601; France 5,180; Cyprus 3,000.
Cement, hydraulic	9,579	10,900	Andorra 9,645; Gibraltar 1,048.
Clays:			
Kaolin	13,937	9,265	West Germany 6,851; Netherlands 2,096.
Bentonite	1,650	2,434	France 1,916; West Germany 331; Italy 180.
Other	1,009	7,290	Italy 6,523; Portugal 300; West Germany 200.
Diatomite and other siliceous earths	631	365	West Germany 165; United Kingdom 140; Netherlands 51.
Diamond, value, thousand pesetas [7] industrial.		503	All to Cuba.
Dolomite	7,496	6,483	Mainly to France.
Feldspar, lucite, nepheline and nepheline-syenite.		600	All to United Kingdom.
Flint	102	1,367	Gibraltar 1,065; Andorra 280.
Fluorspar	101,503	88,001	United States 75,117; West Germany 6,124; Italy 4,794.
Gypsum	4,625	4,769	Andorra 2,969; West Germany 750; Portugal 482; France 300.
Lime, hydraulic	483	486	Andorra 471; Gibraltar 15.
Magnesite, natural	14,951	7,857	West Germany 7,696.
Natural pigments	690	199	Netherlands 95; West Germany 60; Yugoslavia 16.

TABLE 2.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1692	Principal destinations, 1962
Nonmetals—Continued			
Potassium chloride	292,976	228,725	Norway 55,968; United Kingdom 55,392; United States 42,600; Belgium 27,150.
Potassium sulfate	2,700	19,360	United States 13,860; Greece 3,000; Portugal 2,300.
Pyrites thousand tons	1,034	1,022	West Germany 571; France 221; Denmark 100; Belgium 71.
Salt	434,656	511,281	Japan 150,233; United States 65,438; Italy 49,080; Iceland 43,399; Denmark 42,815.
Sand	53,150	63,786	Gibraltar 33,694; Andorra 30,017.
Shale	284	495	Andorra 373; Netherlands 99; West Germany 23.
Stone, dimension:			
Calcareous	11,034	11,956	West Germany 4,507; Italy 3,768; France 1,779; United States 548.
Other	7,228	10,030	Gibraltar 6,341; France 2,296; Italy 1,268.
Talc and steatite	41	212	Mainly to Italy.
Others [8]	350	74	Portugal 39; Sweden 30; West Germany 5.
Mineral fuels:			
Coal, bituminous and lignite	[9] 36,582	15,599	Portugal 14,454; Andorra 1,145.
Coke and coke briquets	27,596	----------	
Petroleum refinery products:			
Gasoline	64,739	54,752	United Kingdom 38,281; Netherlands 16,459.
Aviation gas (jet)	4,023	49,110	Bunkers.
Residual fuel oils	42,088	21,011	United Kingdom 10,742; Netherlands 10,269.
Lubrication oils	1	26	Italy 18; Belgium 7.
Liquefied petroleum gases. cubic meters	8,915	5,940	Algeria 3,358; France 2,582.
Paraffin	567	768	Italy 200; United Kingdom 150; France 148; Netherlands 141.
Other bitumens	430	44	Andorra 21; Portugal 13; United Kindom 10.
Carbon black	1	9	All to Portugal.

[1] Includes 72 tons of matte exported to Belgium.
[2] Less than 15 troy ounces.
[3] Includes 37 tons of coils for rerolling, of which 22 tons went to West Germany.
[4] Includes bauxite (1961), tin, tungsten, titanium, vanadium, molybdenum, tantalum, zirconium and unspecified.
[5] Includes antimony, columbium, cadmium, tantalum, selenium and tellurium, tungsten, and unspecified.
[6] Includes 18.8 tons columbium.
[7] 60 pesetas=US$1.00.
[8] Includes chalk, natural and artificial corundum, and quartz and quartzite.
[9] Includes 15,489 tons anthracite.

TABLE 3.—Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals:			
Aluminum:			
Bauxite	40,222	46,828	Greece 34,355; Jamaica 7,797; Surinam 2,000.
Aluminum and aluminum hydroxide.	83,961	91,117	France 90,922; West Germany 171.
Aluminum scrap	310	981	United States 223; United Kingdom 190; Canada 155.
Metal and alloys, unwrought	3,955	7,459	Canada 7,077; United States 196; Norway 151.
Wrought	1,131	1,880	United States 767; France 350; West Germany 258; Switzerland 178.
Antimony:			
Ore and concentrate	250	589	All from Morocco.
Metal unwrought	43	61	Netherlands 30; West Germany 20; mainland China 11.
Arsenic, white	664	663	France 456; Portugal 200.
Bismuth	23	17	United Kingdom 16.
Cadmium	6	21	United Kingdom 10; West Germany 5; France 5.
Chromium:			
Chromite	16,541	19,658	Republic of South Africa 7,965; Iran 6,259; Turkey 3,179; Federation of Rhodesia and Nyasaland 2,230.
Unwrought	10	6	All from United Kingdom.
Copper:			
Ore and concentrate	50,410	22,909	Cyprus 11,340; Canada 6,408; Italy 3,338.
Matte	2,163	3,204	Cyprus 1,672; Israel 1,477; France 55.
Blister	9,815	18,846	British East Africa 9,220; Turkey 9,131; Mexico 495.
Refined, unwrought	653	4,914	Belgium 2,249; United Kingdom 800; Norway 610; West Germany 584; Federation of Rhodesia and Nyasaland 439.
Copper and alloys, wrought	477	3,870	United Kingdom 2,057; Belgium 600; West Germany 541.
Scrap	10,383	15,719	United States 5,772; West Germany 1,612; United Kingdom 1,596; Canada 1,516.
Gold, semi wrought and wrought.	troy ounces 17,812	26,685	West Germany 13,503; France 12,507.
Iron and steel:			
Iron ore	214,303	252,860	Morocco 202,585; Portuguese Asia 17,665; Brazil 11,913; India 10,351; Liberia 10,221.
Scrap	246,880	306,594	United Kingdom 220,270; United States 66,919; Belgium 11,494.
Pig iron and castings	1,493	3,729	West Germany 1,580; Belgium 1,086; Norway 884; Australia 124.
Shot, grit, pellets, powder, sponge	1,188	853	Sweden 643; France 146; West Germany 32.
Ferroalloys:			
Ferrochromium	1,335	1,683	Norway 683; France 538; Sweden 215; West Germany 111.
Ferromanganese	1,444	1,419	Norway 888; France 415; United States 47; West Germany 45.
Ferrosilicon	145	159	United Kingdom 99; West Germany 47; Switzerland 10.
Ferrotungsten	----------	41	Portugal 22; Czechoslovakia 5; Norway 5; Sweden 5.
Other	461	871	Norway 374; France 136; West Germany 129; Netherlands 76.
Steel:			
Ingots and other primary forms.	366	175,691	West Germany 84,756; Portugal 35,212; Belgium 21,002; France 12,987; Italy 108.
Coils for rerolling	35,389	130,924	West Germany 67,761; Japan 59,121; Belgium 3,936.
Wire rod	397	27,523	West Germany 10,938; France 10,749; Belgium 4,776.
Bars and rods	2,223	25,922	Belgium 9,333; United Kingdom 9,041; West Germany 3,689; France 2,110.
Angles, shapes, sections	8,441	21,621	Belgium 7,653; West Germany 6,446; France 4,616; United Kingdom 2,491.
Plates and sheets, uncoated	44,388	70,625	France 19,129; Belgium 14,662; West Germany 12,077; United Kingdom 9,125.
Plates and sheets, coated	52,026	73,981	United Kingdom 27,309; France 20,604; West Germany 9,185; Italy 7,365.

[3] None reported.

COMMODITY REVIEW

METALS

Copper.—The massive cupriferous pyrite deposits of southern Spain have been exploited for their copper content since ancient times, but output from these deposits has constituted only a small part of the raw material requirements of Spain's copper industry in recent years. In 1963 copper content of domestic ores was equivalent to only 37 percent of blister copper output and less than 15 percent of refined copper production; imports of ores and concentrates, matte, blister

Digitized by Google

copper, and scrap provided the remainder of smelter and refinery copper-bearing raw materials. Even these imports fell short of internal requirements and modest imports of copper and copper alloy semimanufactures contained to supply a part of domestic needs, these imports exceeding all copper exports.

The most important mining concern in 1963 was Compañias Españolas de Minar de Rio Tinto, S.A.; this firm has for a number of years produced over 90 percent of domestic output. Spanish reserves have been estimated to total several million tons of contained copper.

Iron Ore.—Spanish consumption of domestically produced iron ore declined in 1963, as output fell and export increased. An increasing share of domestic requirements was met through imports of higher grade ores than were available internally.

Some higher grade deposits have been depleted to a large extent, but remaining positive and probable reserves have been estimated to total 880 million tons, and inferred reserves are reportedly about 375 million tons. Principal deposits are in the Bilbao-Santander-Asturian area of northern Spain.

Iron and Steel.—The Central Siderurgica, an organization comprised of 21 of the leading private steel producing companies and the State-operated Empresa Nacional Siderurgica (ENSIDESA) dominates the iron and steel industry of Spain. ENSIDESA is part of the Government industries group controlled by the Instituto Nacional de Industria. ENSIDESA, Altos Hornos de Vizcaya, S.A., and Union Siderurgica, S.A. (UNINSA) were the three largest steel producers.

ENSIDESA complex accounted for approximately one-third of total Spanish production of pig iron and steel ingots in 1963. Major facilities of its plant at Ariles in 1962 were two blast furnaces with a total annual capacity of 1,140,000 tons and five acid open-hearth furnaces with an aggregate annual capacity of 900,000 tons. Pig iron production in 1963 was about 650,000 tons, a substantial reduction from 1962 production as a result of shutdowns for furnace repairs.

Altos Hornos de Vizcaya, S.A., with plants at Baracaldo and Sestao accounted for the largest tonnages of iron and steel, among the private companies. In 1963 this company accounted for about one-third of Spain's output of both pig iron and ingot steel. At the end of 1962 major production facilities in Vizcaya's plants consisted of six blast furnaces with an aggregate annual capacity of 650,000 tons, an open-hearth furnace with a capacity of 282,000 tons, four 15-ton Bessemer converters with a total capacity of 300,000 tons, and two electric furnaces with a combined capacity of 16,000 tons; in Sagunto there were three blast furnaces with a capacity of 438,000 tons, eight open-hearth furnaces with a capacity of 384,000 tons, and an electric furnace with a capacity of 1,200 tons.

The Union Siderurgica, S.A., complex consisting of Sociedad Metalurgica Dura Telguera, Fabrica de Mieres, S.A., and Sociedad Industrial Asturiana Santa Barbara, Fabrica Moreda, is Spain's second largest private industry producer of iron and steel. In 1963 its production was a little over 200,000 tons of both pig iron and steel, approximately 10 percent of total production. Company facilities at the end of 1962 included Mieres which has two blast furnaces with a capacity of 122,800 tons and seven open hearths with a capacity of 72,000 tons; Gijon which has two 250-ton blast furnaces with a capacity

Digitized by Google

of 150,000 tons, four basic 60-ton open hearths (160,000 tons), and one 25-ton electric arc furnace (30,000 tons); and La Telguera which has three blast furnaces (annual capacity 346,750 tons), three open hearths (150,000 tons), three Bessemer converters for duplexing (94,500), and a 12-ton electric furnace (21,600 tons).

Other plants with capacities upwards of 100,000 tons are—Echevarria, S.A., at Recalde and Santa Agueda with three blast furnaces (annual capacity 73,000 tons), three open hearths (33,000 tons), three electric furnaces (28,800 tons), and one 12-ton electric furnace (15,000 tons); Moreda y Gijon, at Gijon with two blast furnaces (146,000 tons), three open hearths (150,000 tons), and two electric furnaces (3,600 tons); Nueva Montaña Quijano, S.A., at Nueva Montaña, Santander with one blast furnace (100,000 tons), one 45-ton and one 65-ton basic open-hearth furnace 120,000 tons, three 10-ton Bessemer converters, and one 12-ton electric arc furnace (18,000 tons); Estaban Orbegozo, S.A., at Zumarraga with two 40-ton basic open-hearth furnaces (40,000 tons capacity each), one 50-ton open hearth (50,000 tons), one 6-ton electric arc furnace (7,700 tons), and one 3-ton electric arc furnace (3,000 tons).

Modernization and expansion of Spain's iron and steel industry continued. The impetus for this expansion was the Economic Development Plan which forecast that total demand for steel in Spain would be almost 6.5 million tons by 1972.

New installations entered on service in 1962 included one 20-ton electric steel furnace in Fabrica de Moreda, Factory of Industrias Asturianas "Santa Barbara," S.A., and a rolling mill for the same company, and rolling mills in Material y Construcciones, Duro Telguera, Nueva Montaña Quijano, and Jose Maria Aristrain, S.A.

Installations completed in 1963 included two Linz-Donawitz furnaces (250,000 tons each) by Altos Hornos de Vizcaya, S.A., a structural mill (200,000 tons) by Union Siderurgica, S.A., and a tin-plating mill (80,000 tons) and a Bliss skin-pass mill (100,000 tons) by Laminacion de Bandas, S.A.

Lead.—In 1963 Spain accounted for slightly under 2.4 percent of world output of lead, both at the mine and the smelter stages of production. In metal content of ore mined, this represented a 14.3 percent decline over 1962; in smelter output, a 17.0 percent decline. In spite of the lower level of output in 1963, Spain apparently continued to produce more lead than it consumed, and exports, which were equivalent to nearly 41 percent of smelter output in 1962, continued.

During 1962, lead was produced by 212 mines, including 137 lead mines, 51 lead-zinc mines, 5 lead-zinc-fluorspar mines, 4 lead-zinc-iron mines, and 15 lead-zinc-pyrite mines. Of these mines, 54 lead mines were in Jaén Province, and 37 lead-zinc mines, all lead-zinc-iron mines, and 14 lead-zinc-pyrite mines were in Murcia Province. Over half of the total production came from the lead mines.

The Mantos Ayuler deposit in Murcia Province reportedly has a known reserve of 4 million tons of 2 percent lead ore and an inferred reserve of 40 million tons of 1.5 percent ore. Old mine dumps have been estimated to contain 25 million tons of 1.5 percent lead material which may become economically recoverable. High-grade reserves,

Digitized by Google

which made possible Spain's rank as the world's second largest lead producer during the 1920's, have been largely exhausted.

The most important lead mining companies have been: Sociedad Minera y Metalurgica de Peñarrega, S.A., in the Province of Jaén; Sociedad Minero Metalurgica Zapata Portman, S.A., in Cartagena district, Province of Murcia; and Real Compañia Asturiana de Minas, Sociedad Anonima, in the Torrelaga district, Province of Santander.

The ownership, location, and capacities of primary lead smelters and refineries in Spain were:

Company	Plant location		Annual capacity (metric tons)
	City	Province	
Compañia La Cruz	Linares	Jaén	36,500
Compañia Minero Metalurgica Los Guindos, S.A.	Malaga	Malaga	20,000
Sociedad Minera y Metalurgica de Peñarroya, S.A.	Peñarroya and Santa Lucia.	Murcia	40,000 30,000
Minas del Priorato, S.A.	Bellmunt de Ciurana	Tarragona	6,000
Real Compañia Asturiana de Minar, Sociedad Anonima.	Renteria	Guipuzcoa	14,000
Compañia Sopwith, S.A.	Linares	Jaén	25,000
Industrias Reunidas Minero-Metalurgicas	Asua	Vizcaya	12,000
Total			183,500

Mercury.—Spain contributed substantially to the world supply of mercury in 1963 producing an estimated 22 percent of world output. Virtually all the Spanish production came from the large Almaden mine in the Province of Ciudad Real. The mine was operated by the Spanish State through Minar de Almaden y Arraganes. This mine is considered to be the world's largest potential source of mercury. In the 20th century production from this mine has been over 2 million 76-pound flasks of mercury. Some mercury also was produced by Minar de la Soterraña in Oviedo Province in conjunction with arsenic mining.

Zinc.—Mine production of zinc in 1963 moved sharply upward, reaching a higher level than had been attained since 1955, and exceeding that of 1962 by over 11,000 tons. About 70 percent of metal in ores and concentrates was recovered by Spanish smelters, the balance presumably was exported as in the past. Mine output constituted 2.5 percent of estimated world production in 1963, and smelter output was about 1.8 percent of the world total. Except for the sharp decline in 1962, Spain's mine zinc production has been relatively stable, in the range of 80,000 to 90,000 tons for a number of years, fluctuating less as a result of world price and demand changes than many other significant producers, and generally edging upward. Smelter zinc output has increased 160 percent over that of 1959.

For years the Real Compañía de Minas, S.A., has been the foremost mine producer of zinc ore in Spain; its Recocin mine in Santander Province, accounted for about 70 percent of production in 1962. The Company plant at Recocin is completely modern.

Other important zinc mining companies included Compañía Sopwith and Española del Zinc. In 1962 there were 61 operating lead-zinc mines, of which 37 were in Murcia Province; 5 lead-zinc-fluorspar

Digitized by Google

mines; 4 lead-zinc-iron mines, all in Murcia Province; and 15 lead-zinc-pyrite mines, of which 14 are in Murcia Province. The one mine in Santander Province, however, accounted for 80 percent of the zinc from lead-zinc-pyrite ore. Seventy-eight percent of all zinc production came from lead-zinc-pyrite ore in 1962.

Real Compañía de Minas S.A. continued to operate a smelter at Aviles in Oviedo Province. This facility was Spain's only zinc smelter for a number of years. Beginning in 1959, however, Española del Zinc commenced operations in a new smelter at Cartagena. This plant was especially designed to handle the high-iron zinc concentrates from the mines of the Cortagena-Mazzaron area in Murcia Province.

NONMETALS

Cement.—Cement production has increased steadily; output of artificial cement, which accounts for over 90 percent of combined artificial and natural cement, increased 6 percent in 1963 with respect to 1962 and was 39 percent greater than in 1959. There were 56 plants producing artificial cement in 1962; the Provinces of Barcelona, Madrid, Oviedo, Toledo, and Valencia were the principal producing areas accounting for over half the output of the 28 producing provinces. In spite of increased production, Spain continued to import significant quantities of cement. Over 80 percent of 1962 output of natural cement came from the Provinces of Barcelona, Gerona, and Baleares.

Fluorspar.—In 1963 Spain accounted for 7.2 percent of the total world production of fluorspar. The principal mines were in the Provinces of Barcelona, Cordoba, Gerona, and Oviedo. Major producers were Minerales y Productor Derivados, S.A. and Fluoruros, S.A.

Exports of fluorspar in 1963 decreased 12 percent to 88,000 tons.

Potassium Salts.—After a sharp decline in production in 1962, the potash industry partially recovered with a 6 percent increase in 1963 registering an output of a quarter of a million tons of K_2O equivalent.

Spain's potash deposits are extensive and reserve estimates are upward of 500 million tons containing 15 percent K_2O. The bulk of production comes from Barcelona Province where deposits were first discovered in 1912 and first mined in 1926. Only recently has production commenced in Navarra Province, where deposits were discovered in 1950. Principal companies mining potash are Union Española de Explosives, S.A., Minas de Potosa de Surica, S.A., Potosas Ibericas, S.A., and Explotaciones Polasicor, S.A.

Potassium salts have constituted an important part of Spain's mineral export trade.

Pyrites and Sulfur.—Production of iron pyrites, including cupriferous iron pyrites, declined slightly from the 1962 production level. The largest share of the decline occurred in cupriferous iron pyrite output. Exports of pyrites remained at slightly over 1 million tons.

Elemental sulfur production declined by over one-third, while sulfur imports increased approximately 10 percent, with over one-third coming from the United States.

Spain's reserve of pyrites is among the largest in the world. Most of the deposits occur in Huelva Province in southern Spain. During

Digitized by Google

the last 90 years, over 60 million tons of pyrites have been produced. Reserves have been estimated to total about 250 million tons. The average sulfur content of these high-grade pyrites is about 50 percent. In 1962 Spain produced over 10 percent of the world's pyrites, and only a little over 1 percent of elemental sulfur.

In 1962 almost 95 percent of the pyrites produced was mined in Huelva Province. All the remainder came from Sevilla Province.

The principal mines are operated by Compañia Española de Minas de Rio Tinto S.A., and Compañia de Azufre y Cobre de Tharis. The Seville Sulfur and Copper Co., Ltd., is the principal operator in Sevilla Province.

Over 85 percent of the elemental sulfur is produced by Rio Tinto. Other important producers are Industrial Quimica de Zaragoza S.A., Sociedad Anonima Coto Minera de Hellin, and Romero Hermanos, S.A.

It has been reported that under the influence of the Spanish Economic Development Plan, there are plans to modernize the pyrites mines to increase production of sulfuric acid-based fertilizers.[2]

Other Nonmetallic Minerals.—Spain produces important quantities of limestone, gypsum, and lime, the latter two being minor export items. Crushed and dimension stone are also produced in sizable quantities. The large increase in production of construction materials, over the past 5 years reflects the increased tempo in building.

MINERAL FUELS

Coal.—Production of solid fuels in 1963 slightly exceeded the 1962 level of output. Domestic production, however, was insufficient to satisfy demands and over 1.5 million tons of coal was imported. During 1963 the Spanish coal industry suffered as a result of extensive labor strikes. The coal industry accounted for almost half the employment in the entire Spanish mineral industry.

Petroleum Refinery Products.—There has been a steady increase in refined petroleum products over the past 5 years. In 1963 there was a 21 percent increase in refinery input. Total value of products in 1963 amounted to US$13.5 million. Notable increases in output were gas-oil, up 17 percent, fuel-oil, up 16 percent; and dry gases, up 28 percent.

Spain's daily refinery capacity was rated at 220,000 barrels in 1963. Consumption of crude oil was 158,644 barrels daily. Exports were 24,736 barrels daily of products while imports were 214,400 barrels per day of crude oil and 11,562 barrels per day of products.

The Mineral Industry of Sweden

By E. J. Gealy [1]

MINING and mineral processing continued to be leading industries in Sweden in 1963. Overall industrial production in the country had been consistently rising during the 1958–63 period and in 1963 was estimated to be 25 percent higher than in 1958. The contribution of mining and mineral processing, including iron and steel production, to Sweden's gross national product was approximately 6 percent through 1962; as a result of generally lower mineral commodity prices during 1963, it appears that the share of output value of mining and mineral processing may have decreased somewhat from the previous year in spite of generally higher levels of production quantitatively.

Sweden's total foreign trade, excluding precious metals in ores, bullion, coins, and issued currency, has been in fairly close balance but has continually recorded a net deficit for the past several years. In 1963 imports were valued at SKr17,542 million [2] and exports at SKr 16,573 million. Minerals and metals, including fuels, have been a consistently large item in Sweden foreign trade. Commodities of this type have accounted for almost 30 percent of the total value of imports, whereas they have represented less than 20 percent of the value of exports. These items, as a group, have thus been a major factor in Sweden's net trade imbalance. The dependence of the country upon imports of mineral fuels is exhibited by examining the value of these energy commodities as traded. In 1961 mineral fuels imports were valued at SKr2,045 million, exports at SKr40 million; in 1962 fuel imports were SKr2,150 million and exports SKr49 million. The net trade deficit in fuels alone has been larger than the total net trade deficit of the country. Although the remaining nonmineral and nonfuel mineral commodities have consistently returned a favorable net trade balance, the quantity has been relatively insignificant and the net deficit in mineral fuels is roughly equivalent to the net deficit of total minerals and metals, including fuels.

In recognition of this trade problem, as well as the implications to the country's self-sufficiency position, Sweden has capitalized heavily on its only significant energy resource, hydroelectric power. Sweden uses a high proportion of its energy as electricity, and, of approximately 40 million megawatt-hours of electricity generated in 1963, about 95 percent came from hydroelectric sources. The trade problem is also a factor in the intense Swedish interest in the development of nuclear-fueled powerplants. On July 17, 1963, the country's first

Digitized by Google

nuclear-energy powerplant became critical; the second plant was authorized in 1962 and the design was decided in 1963.

A decline in profit margins caused by rising production costs and stable export prices had the effect of reducing investment in the industrial sector, which includes several mineral processing industries.

GOVERNMENT POLICIES AND PROGRAMS

The Swedish Government has participated heavily in the mining and mineral processing industry through ownership of operating companies. Organizations so controlled function as private companies and compete with those in the private sector. There has been no great growth of Government ownership nor is the position of private industry under pressure from the Government. On the contrary, private investment is encouraged. Any person, by taking out a claim with the appropriate mining inspector, may obtain the right to exploit deposits of most of the metallic minerals and several of the nonmetallic minerals. Since 1938 the State is entitled to a half share of any mining concern, but this does not apply to concerns predating the Mining Act of 1938. Mineral fuels, salt, alum shales, and other commodities may also be exploited by private persons but require a concession granted by the Government. Deposits of any potential nuclear fuel material are more closely regulated.

No fundamental changes in these policies or laws were invoked in 1963 nor was new legislation introduced. During the year the Government granted some forms of direct financial relief to small mining companies faced with difficulty in the ore export market. Trade negotiations by the Government during 1963 reflected obvious concern for the export position of the country's mining industry, both public and private.

The Government program for nuclear energy development advanced with the authorization for construction on several new facilities and the formation of new research organizations. The Government's interest in the available stocks of mineral fuels continued through 1963.

SOURCE MATERIAL

Swedish trade data has been extracted from official Government publications; however, because of a changed pattern of reporting, designed to provide coincidence with reporting of other European countries, the release of official production data has been delayed. The material contained herein in regard to annual output has been gathered from several nonofficial sources, including the annual reports of several of the larger companies. Comparable data were not available for many of the construction materials and for a number of nonconstruction material mineral commodities produced in Sweden in minor quantities. The information presented covers all the major commodities produced and, although estimates have been made in several cases for 1962 and 1963, these are considered to be of the proper order of magnitude.

Digitized by Google

PRODUCTION

Mineral and metal production in Sweden was already at high levels in 1962 and, during 1963, increased moderately in most instances. The most significant gains were recorded in iron ore, iron and steel, mine and smelter lead, mine zinc, and aluminum. As a whole the mineral industry operated at near capacity levels, particularly in the metal smelting sector, with copper being a notable exception. Also prominent among the commodities of which output declined in 1963 were the precious metals. Production of these is a function of the metal values contained in base metal ores, and they are recovered as byproducts at copper, lead, and zinc operations and do not reflect the

general increased trend of the industry. These declines apparently stem from changes in the relative share of total nonferrous ore smelter feed contributed by the several Boliden Mining Co., Ltd. mines, some of which contain considerably higher precious metal values than others. The only other major mineral decline was registered in coal output; the reduction in the tonnage produced in 1963 was a continuation of a long, established trend.

TRADE

Sweden's trade picture changed relatively little in 1963 particularly in metals and minerals. Certain features of international company agreements tend to stabilize the direction and, to a lesser extent, the volume of the movement of some commodities. Sweden acts as a custom smelter of copper for factors in West Germany, and several countries import quantities of Swedish iron ore as part of traditional understandings.

The major problem of 1963, applicable to total trade but particularly to mineral commodities, was the fact that export prices changed little, in fact declined in some cases, while costs of production increased substantially. The Swedish market for iron ore was somewhat depressed during 1963 because of the generally sluggish activity in the European steel industry and because of the technological shift to oxygen steelmaking.

Sweden's major trading partners remained the United Kingdom, West Germany, and the United States. In minerals West Germany continued to rank high as an export market. Much of Sweden's mineral trade is with EFTA (European Free Trade Association) countries rather than EEC (European Economic Community) areas, but satisfactory negotiations were carried out with members of both groups. Sweden's iron and steel industry expressed the belief that the foreign market for high-quality alloy steels would probably improve, while the market for common steels would be more competitive. The increased output of Swedish automobiles raised the domestic demand for flat-rolled steel. While these products were imported fairly heavily during the first half of 1963, operation of the new flat-rolling equipment installed in domestic plants began to be effective in reducing the import demand in the last half of the year.

The value of 1962 metal and mineral exports listed in the tables of this chapter totaled about SKr2,431 million; in comparison, imports totaled about SKr3,993 million. Distribution of value of exports and imports in 1962 by major commodity groups was:

Commodity group	Exports (million kroner)	Imports (million kroner)
Metals:		
Iron, steel, and ferroalloys	1,979	853
Other	353	798
Nonmetals	50	192
Mineral fuels	49	2,150
Total	2,431	3,993

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Scrap	697	835	West Germany 399; Denmark 272.
Unwrought	83	245	Finland 74; West Germany 74; Denmark 37.
Wrought	6,014	7,499	Finland 2,761; Norway 2,144; Denmark 1,017.
Antimony, unwrought	7	10	Denmark 5; Finland 5.
Arsenic, white	10,393	7,843	United Kingdom 4,657; Australia 1,039; United States 714.
Cobalt	15	13	West Germany 12.
Copper:			
Scrap	731	554	West Germany 311; Netherlands 83; Norway 57.
Refined	16,209	16,139	U.S.S.R. 11,936; Norway 1,571; France 1,533.
Alloys	1,773	1,920	West Germany 1,365; Italy 335; Denmark 177.
Bars, rods, angles, sections, wire	18,925	16,849	Norway 8,012; Denmark 7,707.
Plates, sheets, and strip	4,716	4,243	Norway 1,682; Denmark 898; West Germany 800.
Foil	4,482	6,011	United States 2,981; West Germany 2,173; Italy 416.
Other wrought	2,589	2,041	Denmark 708; Norway 669; United States 443.
Gold bullion (approximate)	troy ounces 49,000	52,000	All to France.
Iron and steel:			
Ore and concentrate	thousand tons 20,250	19,396	West Germany 7,954; Belgium-Luxembourg 4,263; United Kingdom 4,247.
Roasted pyrites	do. 181	200	West Germany 189; United Kingdom 11.
Scrap	14,091	11,489	West Germany 7,139; Norway 1,866; Belgium-Luxembourg 1,338.
Pig iron	70,840	34,965	Denmark 10,360; Norway 5,274; East Germany 4,997; West Germany 4,590.
Shot, grit, and pellets	1,610	1,182	Poland 456; Czechoslovakia 302; Switzerland 132; Norway 112.
Powder and sponge	31,302	32,965	West Germany 6,653; United Kingdom 5,748; Japan 3,393; France 3,131.
Ferroalloys:			
Ferromanganese	2,581	2,578	West Germany 1,344; United Kingdom 547; Austria 183.
Ferrosilicon	5,878	4,658	West Germany 3,247; Austria 762; Rumania 238.
Ferrochrome	18,955	17,331	United States 7,685; United Kingdom 5,453; Austria 251.
Ferro-silico-chrome	1,205	2,416	United Kingdom 1,377; Italy 575; Austria 419.
Other	458	664	United States 144; Arabia Peninsula States 89; Switzerland 56.
Steel:			
Ingots	2,055	3,627	Norway 2,511; West Germany 846; Denmark 106.
Blooms, billets, slabs, etc	157,770	115,314	Finland 30,635; Argentina 20,776; India 9,492; France 8,022.
Bars and rods	104,520	109,721	United States 28,380; Denmark 11,668; Finland 9,505; West Germany 9,177.
Wire rod	65,529	59,425	West Germany 16,339; United States 14,232; United Kingdom 8,688.
Angles, shapes, and sections	23,904	27,554	West Germany 10,123; Denmark 4,979; Finland 4,879.
Heavy plates and sheets (uncoated)	105,149	125,010	West Germany 55,620; Norway 20,324; Italy 18,485; Finland 14,876.
Other uncoated plates and sheets	35,317	37,925	Denmark 8,593; Finland 6,225; West Germany 3,876; Norway 2,757.
Plates, sheets (coated), hoops, and strips	31,991	33,888	West Germany 5,784; United States 4,717; Italy 3,558; Norway 3,341.
Railway track material	5,020	29,536	India 14,996; Norway 11,162; Argentina 999.
Tubes, pipes, and fittings	86,449	113,035	U.S.S.R. 25,303; West Germany 17,518; Netherlands 9,341; France 8,544; Norway 8,058.
Castings and forgings	288	704	Denmark 279; Norway 130; West Germany 75.

TABLE 3.—Imports of major metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals:			
Aluminum:			
Bauxite	25,687	24,233	Greece 18,550; British Guiana 5,676.
Alumina	22,744	38,018	Jamaica 27,437; British Guiana 10,306.
Scrap	179	314	Finland 163; Denmark 98; Canada 20.
Metal and alloys unwrought	24,022	30,824	Norway 14,106; Canada 10,347; United Kingdom 1,363; U.S.S.R. 1,274; Denmark 1,232; Switzerland 1,063.
Semimanufactures:			
Plates and sheets	9,329	10,107	Belgium-Luxembourg 4,282; United Kingdom 1,849; Austria 746.
Other	4,009	4,099	West Germany 1,545; United Kingdom 631; Switzerland 516; France 323.
Antimony, unwrought	345	392	Mainland China 354.
Arsenic, white	2	3	(1).
Cadmium, unwrought	131	104	Norway 63; Poland 22; U.S.S.R. 10.
Chromium:			
Chromite	106,872	110,996	U.S.S.R. 51,325; Yugoslavia 23,008; Turkey 15,561; Federation of Rhodesia and Nyasaland 8,699.
Metal	76	33	United Kingdom 21; West Germany 7.
Cobalt, unwrought	313	152	Belgium-Luxembourg 120; Canada 8; Norway 7.
Copper:			
Ore and concentrate	18,696	21,635	Ireland 5,671; Norway 4,611; Chile 3,814; Cyprus 2,829; Morocco 2,169.
Matte	8,294	9,404	France 6,108; Denmark 3,061.
Scrap	1,503	1,522	France 372; Norway 362; Denmark 283.
Refined, unwrought	67,023	70,253	Chile 24,588; Federation of Rhodesia and Nyasaland 18,976; Belgium-Luxembourg 12,885; Canada 4,982.
Other, unwrought	5,352	1,906	Chile 1,358; France 547.
Alloys	4,531	3,053	United Kingdom 2,085; Norway 457; Belgium-Luxembourg 217.
Copper and copper alloy, semimanufactures	10,113	9,496	West Germany 2,397; Finland 2,309; United Kingdom 1,294; Belgium-Luxembourg 1,014.
Gold:			
Ore and concentrate	496	1,012	Bulgaria 867; France 75; Upper Volta 68.
Bullion, troy ounces	52,000	354,000	Mainly from United States.
Iron and steel:			
Ore and concentrate, thousand tons	4	3	All from Denmark.
Roasted pyrites, do	19	20	Norway 19
Scrap	166,537	29,410	United States 12,316; United Kingdom 10,416; Denmark 2,836; West Germany 1,971.
Pig iron	130,497	182,885	Finland 70,746; U.S.S.R. 51,807; West Germany 18,331.
Spiegeleisen	141	102	All from West Germany.
Shot, grit, and pellets	3,082	2,909	United Kingdom 1,929; West Germany 401; United States 178.
Sponge and powder	4,560	548	United States 529; United Kingdom 13; West Germany 4.
Ferroalloys:			
Ferromanganese	10,979	10,142	Norway 4,506; U.S.S.R. 3,100; Republic of South Africa 884; France 800.
Ferrosilicon	6,316	6,141	Norway 5,171; East Germany 761; West Germany 149.
Ferro-silico-manganese	3,332	3,641	Norway 3,395; United States 240.
Ferrochrome and ferro-silico-chrome	9,030	3,537	Norway 2,070; Yugoslavia 697; Poland 350; Japan 260.
Other	2,525	1,146	West Germany 224; Czechoslovakia 170; France 158; Austria 139; United Kingdom 128.
Ingots, and equivalent primary forms	35,824	12,438	Norway 4,976; United States 4,305; West Germany 2,295.
Bars and rods	102,555	82,281	Belgium-Luxembourg 21,986; France 14,138; West Germany 11,716.
Angles, shapes, and sections	144,424	137,856	Belgium-Luxembourg 50,113; West Germany 46,042; Norway 14,439.
Plates and sheets	498,329	438,673	United Kingdom 84,434; West Germany 68,723; Belgium-Luxembourg 67,121; Poland 166,741.
Tinplate	51,774	56,757	France 24,063; United Kingdom 20,999; United States 5,367.

COMMODITY REVIEW

METALS

Arsenic.—For many years, Boliden Mining Co., Ltd. (Boliden Gruvaktiebolag), has recovered crude arsenic oxide at its Rönnskär smelter, chiefly from the complex nonferrous ores of the soon-to-be-exhausted Boliden mine. The quantities recovered have been far in excess of the quantities the market has been able to absorb, and Boliden has stored the excess material in silo-type structures. Reportedly 300,000 tons or more of crude arsenic oxide are on hand. Thus, in spite of the impending closure of the foremost mine source of arsenic, appreciable stocks of material are available for processing at Rönnskär. By 1963, Boliden had completed its new arsenic refinery, which doubled treatment capacity to 30,000 tons per year.

Copper-Lead-Zinc.—The Boliden Mining Co., Ltd. (Boliden Gruvaktiebolag), constituted almost all of the base metal industry of Sweden. In 1963 the company operations continued almost unchanged with only slight increases. Prospecting and development work increased. In the Långdal mine, which is scheduled to replace the nearly exhausted Boliden mine in the late 1960's, development was almost to the deepest communication level at 405 meters; at Kristineberg examination at depth commenced; at Laisvall the 1.6-kilometer-long access tunnel was completed, and the new concentrating plant was run in, resulting in production of over 1 million tons of ore.

In spite of the high level of production of mine copper, lead, and zinc, the company increased its reserves of ore during the year. Underground exploration costs of potential ore bodies and exploitation costs for small ore bodies were reduced in part through use of mobile mine plants and head frames. These installations can be shifted with reasonable ease from an unsuccessful exploration site or worked out ore body to a new site without the usual costs of dissembly and reassembly. The scheme has been pioneered by Boliden because of the numerous small ore bodies on which it holds leases. Mining operations were hampered somewhat by a shortage of labor in 1963.

Copper smelting at Rönnskär increased to a new high although mine copper output fell slightly. This was possible because of the greater treatment of purchased ores and secondary material which increased from about two-thirds of the total raw material in 1962 to about three-fourths in 1963. Improvements were made at the lead smelter which reduced costs and increased production. Boliden made an agreement to take over half the shares in the Norwegian Zinc Co. for which 125,000 Boliden shares would be transferred to Norwegian Zinc's parent company, Compagnie Royale Asturienne des Mines of Belguim. Boliden has no zinc smelter and the acquisition of the Norwegian company was considered a natural step. It was announced that Norwegian Zinc would increase its capacity by a third to 64,000 metric tons per year.

At Rönnskär, Boliden was investing the equivalent of US$7.2 million in a slag-fuming plant for the recovery of lead and zinc from copper slags. A mixture of pulverized coal and air will be blown through molten copper slag extracting the lead and zinc content as

Digitized by Google

metal fumes. These fumes will be oxidized into dust, collected and treated. The plant is designed to treat 200,000 tons of slag per year with an expected annual recovery of 20,000 to 25,000 tons of zinc clinkers and 6,000 to 7,000 tons of lead dust. The products will be exported for further processing.

Iron Ore.—Output of iron ore was pushed to highest levels of record primarily by the Government-owned Luossavaara-Kiirunavaara AB (LKAB), the country's largest producer. At Kiruna the 13.1 million metric tons mined during the year came largely (11 million tons) from underground extraction. During 1963 the shaft was enlarged and a crushing station was being installed at the 420-meter level to crush to 70 millimeters rather than to 100 millimeters as previously done. Construction of the new pelletizing plant was begun at Kiirunavaara just south of the present central plant. The facility was ordered from Head Wrightson Iron and Steel Works Engineering, Ltd. Upon completion in 1965 at an estimated cost of SKr90 million (almost US$18 million), the plant will have a capacity of 1.5 million tons of pelletized ore per year. This plant supplants the one planned earlier for the Svappovaara field and will handle much of the mined product from that area. Later a 900,000-ton plant is to be built at Svappavaara. LKAB had a capacity of 350,000 tons of pellets at Malmberget and was expanding that plant to a 500,000-ton-per-year capacity.

Swedish producers of iron ore for export experienced difficulties during the year as a result of declining prices (5 to 7 percent lower than in 1962) and because of the shrinking market for Sweden's high-phosphorus iron ore, particularly in West Germany, as new oxygen steel facilities put heavy competitive pressure on the Bessemer steelworks. Some of the smaller companies in Sweden were already in financial difficulty and one, the State-owned Statsgruvor AB, asked for SKr6 million from the Government to cover anticipated losses for the next few years.

Swedish companies have recognized the need to improve mining efficiency and a move by LKAB to establish a centralized traffic control (CTC) equipped for data processing is one example of the methods being used to cut costs. Information on positions of train sets, the level of filling in shafts and bunkers, and analysis data will be fed into the center which will control ore haulage and hoisting in the mines and will be tied into the surface lines of the Swedish State Railways serving the mines and beneficiating plants as well as those over which the product is shipped.

As of 1963, one of the smaller producers of iron ore, Stora Kopparbergs AB was producing high-grade iron concentrates at 300,000-ton-a-year rate in its new Risberg mill. The products supplied about a third of the feed for the company's Domnarfvets Jernwerk pig iron blast furnaces. The plant uses ore from the Grängesberg field in central Sweden; this material is a mixture of hematite and magnetite and is high in phosphorus. The Risberg mill uses fine grinding to −8 mesh and magnetic separation to produce a 65-percent iron concentrate. Tailings from the first separation are treated in 80-turn Humphreys spirals. The Humphreys concentrate is mixed with the

Digitized by Google

magnetic concentrate and the final tailing dewatered in top-feed filters of high efficiency.

The iron ore prospecting program of recent years was in its final stages in 1963. The work was being done by LKAB for the Swedish Geological Survey in the Svappavaara area and in the Kaunisvaara field in Pajala.

Iron and Steel.—Increased economic activity during the latter half of 1963 was reflected by the almost full use of Sweden's iron and steel capacity and resulted in the record high output for the year. The increased domestic capability for the production of flat-rolled products was indicated by decreased import demand for the items during the final semester. In general and in spite of the increased demand, steel prices were unsatisfactory from a producer's viewpoint during the year. Prices for some commodities were reduced to 10-year lows. Greater efficiency and plant rationalization were relied upon to combat the squeeze between rising costs and reduced per-unit income. The problem of the Swedish industry was complicated by the decision of EEC countries to raise tariffs on some steel products; however, Sweden's total steel exports were higher than in 1962.

Pig iron output increased relatively moderately in support of the larger steel output. The proportion of scrap used in steel furnaces increased. Sponge iron production was only slightly higher in 1963 than in 1962 as facilities operated at capacity both years. The Höganäs Group revamped its operation by installing a new iron-tunnel kiln, and total capacity of the company was increased by about 40,000 tons per year. It was planned that the old pit-kiln would be held in reserve.

The new Kaldo and LD furnaces took over a larger part of steel-making production, and their output in 1963 increased 165 percent over the 1961 level.

Uranium.—Sweden's nuclear power program is in the hands of a Government company, Atomenergi AB, which functions as a profit and loss organization although its income is derived primarily from Government grants and subsidies. Some funds have been obtained from the sale of radioactive isotopes and from the charges for services to other Swedish companies. In 1963 Atomenergi reported good progress on the uranium mill at Ranstad and the beginning of the production of refueling elements and enriched uranium dioxide elements for testing. The major accomplishment of the year was the success of going critical at the Ågesta power station and district heating plant on July 17, 1963. This plant was a joint venture of Atomenergi, the State Power Board, and the Stockholm Electricity Authority. Also in 1963, the Government approved the design of the Marviken power station at Vikbolandet, Sweden's second such plant.

Although Sweden's early work in nuclear power was accomplished with imported fuel from the United States, domestic resources were being worked in 1963. Uranium shales at Mt. Billingen were being exploited, and the new Ranstad mill was expected to produce 120 tons of uranium concentrates per year from 850,000 tons of shale. It was planned that some type of breeder reactor eventually would be used with the consequent recovery of plutonium. When this is accom-

Digitized by Google

plished, Sweden will be virtually self-sufficient in terms of nuclear fuels.

MINERAL FUELS

Sweden remained almost completely without domestic sources of mineral fuels in 1963. Indigenous resources include bituminous coal and oil shales; however, Sweden's demand for mineral fuels continued to be supplied almost entirely by imports. Production of coal from domestic deposits, done solely by the Höganäs Group, appears to be dwindling to an insignificant point, and operation of the Kvarntorp shale oil plant at capacity provided only about 1 percent of the country's petroleum demand. In 1963 the ready availability of fuel oil at attractive prices, even though imported, was held responsible for the diminution of the coal requirements. Most of the gas used in Sweden was obtained from the conversion of coal in municipal gas plants. Water gas, butane, propane, and other sources made up the smaller part. The use of liquefied petroleum gas increased rapidly and has found application in industry for lead smelting.

Swedish oil shale production operations have been in economic difficulty for many years. The industry was begun to augment the sharply reduced imports of petroleum during World War II and has continued to operate since, although almost always at a deficit. Over the 15-year span ending in 1962, the total accumulated losses of the Kvarntorp plant exceeded SKr100 million in spite of the expenditure of over SKr180 million on improvements. In 1962 the Government authorized closing of the shale oil operation, and during 1963 the volume of retorting of shale was being reduced. Certain chemical byproduct operations of the plant were continued although the fundamental shift was away from shale oil toward crude petroleum for feedstocks.

An expansion program at the important Nynas Petroleum AB refinery of the Axel Johnson group at Nynashamn was completed, raising this refinery's daily capacity to 30,000 barrels and the daily national capacity to 67,900 barrels. The country's other major refinery, Shell's Gothenburg plant, apparently remained unchanged. British Petroleum announced plans for the erection of a major new refinery at Hisingen. This facility, with a planned daily capacity of 50,000 barrels, is expected to cost about US$800 million. The nearby port of Gothenburg reportedly will spend an additional US$12 million on harbor facilities to accommodate larger tankers than it can now handle.

The Mineral Industry of Switzerland

By Walter C. Woodmansee [1]

SWITZERLAND'S diversified industries remained heavily dependent on foreign supply for most mineral commodities during 1963. Despite the country's general lack of mineral resources and its small metal-producing industry, recent developments in mineral fuels have been significant. The trend continued toward greater emphasis on liquid fuels rather than solid fuels for production of energy. As consumption of refined petroleum products expanded further, Switzerland's first oil refinery went into production; others are planned for construction during 1964–65. Crude oil supply would probably come largely through Western Europe's new pipeline system, which was under construction during 1963. Several companies continued oil exploration and distribution activities in Switzerland.

Total value of metal and mineral output in Switzerland during 1963 is not known but would be less than 1 percent of the gross national product, which was SwF41.9 billion [2] in 1962 and continued an upward trend in 1963.

Only a small part of Switzerland's labor force has been involved in actual primary metal and mineral production, but metal goods manufacturing plants and other operations processing metal and mineral commodities were more significant employers. Of a total industrial employment of 750,500 in 1962, only 425 persons were engaged in mining and quarrying; a small but increasing number were employed in petroleum refining; about 100,000 were employed in the metallurgical industry including manufactured metal product plants; and 26,000 to 27,000 were engaged in the construction materials, nonmetals, and earthenware industries.

GOVERNMENT POLICIES AND PROGRAMS

Mineral resources have been explored and exploited by private industry under cantonal concessions, except for salt mining, which is in the hands of cantonal officials. The Rhine salt industry has been organized as a corporation controlled by Swiss cantons.

The Swiss Government continued to encourage private foreign investment in the country's new oil-refining and distribution industries. New companies engaged in exploration and refinery or pipeline construction in Switzerland must be at least 50 percent Swiss owned ac-

cording to national law; other legislation governing exploration for or development of oil deposits is cantonal, and regulations have varied widely.

SOURCE MATERIAL

Most production and trade data are from official Swiss sources through 1962. Most production figures for 1963, however, are based on nonofficial sources or are estimates. Production of secondary nonferrous metals and a few nonmetals and fuels is not available, apparently because the producing companies do not release these data.

PRODUCTION

Aluminum and iron and steel remained the only major metals produced in quantity. The iron and steel industry showed little change during 1963, but production of aluminum ingots continued an upward trend. Among the few nonmetals and mineral fuels produced, little change took place during 1963. Cement output reached a peak in 1962 and declined slightly during 1963, owing to lower demand for cement in hydroelectric powersite construction. Output of manufactured gas and gas-plant coke continued at a high level, while output of asphalt, tar, and pitch remained small.

Production of refined petroleum products commenced during 1963 with completion of Switzerland's first oil refinery. Future production from this refinery and from others in the planning or construction stages during 1963 should improve the national income from minerals during the next few years.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Aluminum	34,370	39,730	42,210	49,570	[2] 61,180
Copper, smelter	----------	----------	1,800	[3] 800	----------
Iron and steel:					
Iron ore—thousand tons	60	125	86	104	96
Pig iron—do	40	50	50	50	42
Ferroalloys (ferrosilicon)—do	4	3	4	5	2
Ingots and other equivalent primary forms—thousand tons	244	249	270	290	295
Castings—do	14	15	16	16	15
Nonmetals:					
Cement	2,683,169	3,036,148	3,601,167	3,725,863	3,581,330
Lime, hydraulic	133,565	168,016	185,666	192,601	184,426
Salt	137,225	149,311	157,277	167,943	185,288
Slate [4]	905	737	751	450	458
Mineral fuels:					
Asphalt	[5] 15,000	15,414	13,229	[5] 13,000	[5] 13,000
Coke, gas plant	467,941	483,811	479,743	496,322	[5] 498,000
Tar and pitch	27,035	29,019	27,729	27,505	[5] 27,000
Gas, manufactured—million cubic feet	12,088	12,289	12,155	12,717	[5] 12,800

[1] In addition to the commodities listed, several metals were produced from scrap, including copper, magnesium, nickel, and zinc. Gypsum, coal briquets, and peat were produced, but output is not reported. Switzerland's first oil refinery went on stream in September 1963, but its output has not been reported.
[2] Includes superpurity aluminum.
[3] Production terminated May 1962.

TRADE

Switzerland's trade deficit in metals and minerals continued in 1963, probably differing little from that of 1962, the last year for which complete data are available. In 1962, exports of metals and minerals were valued at only SwF465.5 million, while value of imports was SwF2,647.5 million. Metal and mineral imports accounted for 20 percent of the value of Switzerland's total imports of all goods in 1962; the corresponding figure for exports was only 4 percent. Metals, including ores and scrap, were the highest valued group of mineral imports (SwF1,485.9 million) and consisted principally of iron and steel semimanufactures; imports of mineral fuels, chiefly petroleum products, were valued at SwF866.9 million; and the nonmetals, chiefly diamonds, were valued at SwF294.7 million.

Metals, metallic ores, and scrap also accounted for by far the greatest part of the value of metal and mineral exports, totaling SwF303.6 million in 1962, principally in aluminum, gold, and iron and steel products; exports of the nonmetals, largely diamonds, were valued at SwF157.2 million, and exports of mineral fuels, largely petroleum coke and lubricants, were valued at SwF4.7 million.

Tonnages of metals and minerals exported during 1962 showed little significance change from those of 1961. Imports of alumina, aluminum ingot, and aluminum semimanufactures increased appreciably during 1962, but imports of refined copper and slab zinc were down. Imports of gold bullion and of steel ingots and some semimanufactures were much higher in 1962. Among the nonmetals and mineral fuels, cement imports increased more than 60 percent, and imports of residual fuel oil, lubricants, and petroleum coke also were considerably higher than in 1961.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Bauxite	--------	40	Mainly to West Germany.
Alumina	32	59	Do.
Ingots, including scrap	6,079	8,563	West Germany 4,587; Italy 1,716; Sweden 1,099.
Semimanufactures	15,111	15,281	Netherlands 2,194; United States 1,395; Nigeria 1,002.
Antimony	[1] 19	12	Mainly to West Germany.
Copper and copper alloys:			
Scrap	535	1,830	Italy 793; West Germany 727; Belgium-Luxembourg 173.
Unwrought	1,652	2,063	West Germany 1,215; Italy 800.
Semimanufactures	8,762	7,851	United States 3,368; Italy 1,494; Israel 662.
Gold:			
Scrap---thousand troy ounces	4,311	3,274	West Germany 1,725; France 696; Belgium Luxembourg 607.
Bullion and other un- do	244	272	Mainly to West Germany.
wrought.			
Semimanufactures---do	39	34	Denmark 20; France 3; Italy 2.
Iron and steel:			
Iron ore	61,282	75,445	Mainly to West Germany.
Scrap	6,253	7,082	Italy 3,811; West Germany 2,160; France 687.
Pig iron [2]	1,127	999	Pig iron: 80 tons to Austria. Other: France 352; West Germany 296.
Ferroalloys	11,776	9,073	West Germany 6,015; Italy 2,435; Austria 539.
Steel:			
Ingots and equivalent primary forms.	131	435	Mainly to Italy.
Semimanufactures, low- and medium-carbon unalloyed steels:			
Rods, bars, angles, shapes, sections.	8,113	7,855	Italy 3,999; Austria 1,824; Belgium-Luxembourg 639.
Flat rolled	2,070	1,597	Italy 470; Denmark 346; West Germany 209.
Wire	1,350	1,156	Italy 316; West Germany 260; Belgium-Luxembourg 128.
Rails and railway track materials.	125	55	Austria 30; Canada 24.
Tubes, pipes, fittings	19,108	20,438	United States 5,342; Peru 2,908; France 2,742; Netherlands 1,961.
Castings and forgings	1,583	1,681	West Germany 809; Netherlands 232; Austria 107; France 100.
Semimanufactures, high-carbon and alloy steels.	1,018	1,032	Italy 594; West Germany 134; France 130.
Lead:			
Scrap	2,126	2,415	Mainly to Italy.
Unwrought	6	1	Mainly to United Arab Republic.
